This operation is the weak point of the present naphthylamine process, for, however carefully conducted, there is always an unavoidable loss due to the conversion of some of the naphthylamine into naphthalene and other products by the heated Fe_3O_4; this is less the quicker the naphthylamine can be removed from the retort. The mass is spread out in thin layers upon iron trays, which are placed on shelves within the retort; the latter is heated strongly by direct firing, whilst superheated steam is passed through it. The naphthylamine is condensed in a worm, the surrounding water being kept at 60° C. It is separated from water, dried by heating with dry steam, and distilled in an ordinary wrought-iron retort. It then forms the ordinary commercial product; it is not quite pure, but contains small quantities of naphthalene.

The yield is fairly good, though considerably below the theoretical. The iron residue left in the retorts contains much reduced iron, which renders it strongly pyrophoric.—A. G. G.

Improvements in the Production of Colouring Matters or Dyestuffs. C. D. Abel, London. From C. Roth, Berlin, Germany. Eng. Pat. 43*, Jan. 1, 1886. 6d.

THE emendation consists in the deletion of a misprint. (See this Journal, 1886, 662.)—T. L. B.

A Process for the Manufacture of Anthraquinone. J. Imray, London. From A. F. Poirrier and D. A. Rosenstiehl, Paris, France. Eng. Pat. 8431, June 11, 1887. 4d.

IT is proposed to oxidise anthracene in a solution of ferric sulphate in the following manner:—50 kilos. of pure anthracene are introduced into a close vessel lined with lead containing 2000 to 3000 litres of a solution of ferric sulphate of from 28—45° B. The mixture is heated for about 72 hours at 120—150°, while compressed air is injected to maintain the ferric sulphate at its full degree of oxidation, so that at the end of the operation ferric sulphate remains ready for further use, the anthracene and its associates being thus virtually oxidised by the injected air, the ferric sulphate serving merely as a carrier of oxygen.—D. B.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

The Chemistry of the Cotton Fibre. A paper read before the British Association, Manchester, 1887, by Dr. F. H. Bowman.

THE author proceeds to point out that our investigations in regard to the cotton fibre must embrace its mechanical and chemical structure. The microscope has enabled us to unfold the former, and the science of chemistry to reveal the latter. After speaking of the mechanical structure, he proceeds to point out how cotton, in common with all vegetable substances, has for its base the substance cellulose, to which the formula $C_6H_{10}O_5$ has been assigned. After referring to the results of the analysis of various kinds of commercial cotton, he proceeds to show that there is strong reason to suppose that the fibre, as met with under ordinary circumstances, is really composed of a series of bodies more or less corresponding to this empirical formula, but differing from it in regard to the arrangement of the hydrogen and oxygen atoms within the molecule, and thus constituting a series of celluloses which have a distinct differentiation rather than one single definite composition. He also points out how, having due regard to the atomicity of the constituents of the typical cellulose molecule, it is almost impossible to conceive that the hydrogen and oxygen are arranged in the molecule in the same atomic combination as water, although that body is always associated with the fibre to the extent of from 5 to 7 per cent., and hence concludes that this water of hydration is not an essential constituent of the cellulose molecule. After summing up our knowledge of the general chemical characters of the cotton cellulose, reference is made to the hydration and dehydration changes of which the cellulose molecule is capable, as exhibited in recent researches on this subject, specially with regard to those conducted by M. Witz, and Cross and Bevan, on the formation and reactions of oxy-cellulose. The behaviour of this body, as distinguished from cellulose and the reactions of the latter when treated with acids and alkalis, are then discussed, and the light which these throw on the probable constitution of commercial cotton is pointed out. Considerable stress is laid upon the fact that the cotton fibre always contains mineral matter to the amount of about 1 per cent. as an integral part of its structure, and the importance of this as a factor in the chemical reactions of the cotton fibre is insisted upon, and various researches which give evidence of this are mentioned. Finally, the author points out the invariable presence of oily, fatty, and waxy matter along with commercial cotton, and the necessity for due consideration of this fact in the methods employed in manipulating the fibre for technical purposes.

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

Improvements in Bleaching and Apparatus therefor. J. H. Johnson, London. From E. Hermite, Paris. Eng. Pat. 13,929, Oct. 21, 1884 (Amended Specification). 11d.

IN this amended specification the inventor withdraws his claim to the use of chlorides of calcium and aluminium, and confines himself to the employment of magnesium chloride for bleaching purposes, and that *only when used in the particular manner described by him.* He also withdraws the claim for its employment as a bleach for paper pulp. For description of the apparatus employed, see this Journal, 1885, 673—674.—O. H.

An Improved Process of Colouring or Producing Coloured Designs upon Celluloid and Analogous Products. A. M. Clark, London. From La Compagnie Française du Celluloid, Paris, France. Eng. Pat. 9874, July 31, 1886. 6d.

THIS invention relates to a process for producing fast and washable coloured designs upon celluloid and other analogous products. By analogous products are understood plastic substances with a base of nitrocellulose, as, for example, the substances known in commerce under the names of fibrolithoid, lithoxyl, zylonite, ivorine, and pyroxylin. The process depends on the action of the three agents—heat, pressure, and steam. A vehicle or temporary support is used for receiving the coloured design, and transferring the same. Good results have been obtained by using the ordinary printed calicoes of commerce, which readily transfer their colours to celluloid. This process is distinct from those in use for colouring celluloid, where this operation is performed by incorporating colouring matter, or by immersion in an alcoholic solution or dye, or printing or painting by known means giving results destroyed by friction.
—H. A. R.

A New Process for Fixation of the Colouring Matters by Oxidation at High Temperature of the Textile Fibres. C. Collin and L. Benoist, Paris, France. Eng. Pat. 6737, May 7, 1887. 4d.

THE inventors claim "the application of heat for the oxidation or fixation on textile fibres—when taken out from cold or hot vats—of indigo or any other colouring matter, with which the fibres are impregnated." The fibres or tissues are drawn from the vat through squeezing rollers, and put on heated metal rollers, whereby the liquid remaining in them is converted into steam, and "a violent escape of vapour takes place, which, mixed with air, will oxidise or fix the colouring matter on the fibres or tissues."—T. L. B.

Improvements in Dyeing and Scouring Yarns. C. L. Klauder, Philadelphia, U.S.A. Eng. Pat. 8803, June 18, 1887. 8d.

THE invention consists in the use of a wooden or other suitable circular frame or wheel, to which two concentric sets of transverse bars are adapted to support the yarns. The skeins are stretched from one set of bars to the other, and caused to move by the rotation of the bars. On causing the wheel to turn round in a dye-vat the yarns are alternately immersed in the dyebath and exposed to the atmosphere. The claims are fully set forth under eighteen heads. Drawings are given.—T. L. B.

Improvements in the Manufacture of Bleaching Liquid. A. Brin, London, and L. Q. Brin, Paris. Eng. Pat. 11,891, Sept. 18, 1887. 4d.

AN aqueous solution of hydrochloric acid is charged with oxygen under pressure until it becomes saturated. The liquid thus formed exhibits marked bleaching properties, and is retained in closed vessels under pressure until required for use, when it may be employed for bleaching after the same manner as hydrogen peroxide.—S. H.

VII.—ACIDS, ALKALIS AND SALTS.

On the Manufacture of Salt near Middlesborough. Sir I. Lowthian Bell. Proc. Inst. Civ. Eng. 1886–87.

THE existence of salt beds at the mouth of the Tees was first ascertained in 1859, when Messrs. Bolckow, Vaughan & Co., sinking a deep well at Middlesborough in hopes of getting water for steam purposes, came, at a depth of 1200 feet, upon a bed of rock salt 100 feet thick. This point may be regarded as the south-east corner of a parallelogram, having a length of at least 3¼ miles, and a breadth of at least 2 miles, over the whole of which the salt deposits are known to lie, and each square mile of which probably contains 100,000,000 tons. The average thickness of the bed seems to be about 100 feet, and at the most northerly hole it is reached at a distance of 900 feet from the surface, or 300 feet less than in the original hole of Messrs. Bolckow, Vaughan & Co. The inference that the bed sinks as it goes southward is borne out by the depth at which salt has been found in the intermediate holes. The district (see map) belongs geologically to the new red sandstone formation. On the right bank of the river this rock underlies the Lower Lias beds (which here form the Cleveland Hills); on the left bank it gradually rises till it reaches the surface near Hartlepool. Nearly a dozen years after Messrs. Bolckow, Vaughan's discovery, the firm of Bell Bros. put down an exploring hole 1314 yards from that first sunk, in a direction a few degrees east of north. Here they practically demonstrated the possibility of raising the salt in the form of brine by a method which was then working at Nancy, in France, and which will presently be described. The boring was performed by the Diamond Rock Boring Company, and specimens of the strata penetrated were obtained in short lengths of a cylindrical form. The boring was continued for 150 feet below the salt bed, and satisfactory proof obtained of the existence of the magnesian limestone below the red sandstone. Considerable quantities of inflammable gases escaped from this bore-hole, but whether they indicated merely the presence of bituminous shales, or whether they originated in coal measures lying below the magnesian limestone, there was no means of deciding. Besides Messrs. Bolckow, Vaughan, and Bell Bros., the Newcastle Chemical Co., the Haverton Hill Salt Co., Messrs. Tennant & Co., and Messrs. Casebourne & Co., of Hartlepool, have salt wells at work. There are supposed to be altogether 20 holes, of which seven are lying idle from accidents of various kinds. The quantity of salt raised per week is estimated at from 2750 to 3000 tons. Brine when saturated contains 26½ per cent. of its weight of salt, and has a sp. gr. of 1·204. The principle adopted in working the wells is to make the fresh water running in lift the brine as far as the difference in sp. gr. will allow. From the above data it will be seen that a column of water 1200 feet high will support a column of brine 997 feet high—that is, will bring it within 203 feet of the surface. From here it is pumped by ordinary means. In practice the operation is performed as follows:—A hole of, say, 12 inches diameter at the surface is continued a certain distance down. Then a wrought-iron tube is dropped down the hole to support the sides. The boring is continued and new supporting or retaining tubes dropped down, one within the other, till the salt bed is penetrated, and the lowest length of tube fixed by entering a short distance into the limestone. That portion of the tube which passes through the salt is pierced with apertures. Within this tube is lowered a second one, having a diameter from two to four inches less than that of the outer tube, and provided with snore holes in its lower portion, Fresh water is fed down the annular space between the two tubes, the inner of which serves for raising the brine. The pump which completes the elevation is an ordinary one, provided with a bucket and clack, which are placed some feet below the point to which the brine is raised by the fresh water. The pump is provided at the surface with a plunger, which forces the brine into an air vessel for distributing purposes. It is obvious that the amount of salt raised will depend chiefly upon the surface exposed to the fresh water, and increases with the cavity formed by the dissolving action of the latter. This cavity takes the form of an inverted cone, which increases the danger of accidents ensuing from the falling in of the outlying rock. This danger is greater from the fact that in many places the covering bed of sandstone, some 40 feet thick, is interstratified with soft marls, which are affected by the inflowing water. In some places the rock salt contains a good deal of earthy matter, and this may account for the diminution of strong brine sometimes observed. Another cause of this is probably the presence of defects in the screwed joints of the pump, which allow fresh water from the annulus to mingle with the brine. In connection with this system of salt raising another question will probably soon arise—viz., with regard to the right of a man to raise salt produced under the lands demised to his neighbour. The brine as delivered from the wells is run first into settlers (where the earthy matter is deposited) and thence into evaporating pans 60 feet by 20 feet by 2 feet. The heat applied varies according to the purpose for which the salt is intended. Table salt is required of fine grain, and the evaporation is carried on much more rapidly than in the case of fishery salt, where large grains are preferred. For salt for soda works, which is intermediate, the pans are kept at about 196° F. The salt is fished out every other day. Messrs. Bell Bros. and Bolckow, Vaughan perform some of their evaporation with waste heat from the blast furnaces. The other firms use ordinary fires of small coal. The discovery of the South Durham Salt Beds has been a great boon to the soda makers on the Tyne. The old Leblanc process only lives by virtue of its rivals' inability to produce bleaching powder, and this reduction in the price of salt comes as a most welcome and timely aid towards keeping back the shadow on the dial yet a little longer.—A. R. D.

On the Formation of Saltpetre. A. Celli and F. Marino-Zuco. Chem. Zeit. **11**, 151.

THE author finds that traces of saltpetre are formed in pure sand wetted with ammonia salts, even when bacteria germs are carefully excluded; in the presence of bacteria a considerable quantity is produced. It is remarkable that, whereas many kinds of bacteria assist the formation of saltpetre, others—such as *Bacillus saprogenus aquatilus*, *Bacillus fluidificans*, *Micrococcus luteus*—not only form no nitrates, but even possess the power of decomposing them. This at least is the case in gelatine solutions; but when they are cultivated on potato-slices they assist the formation of the nitrate.

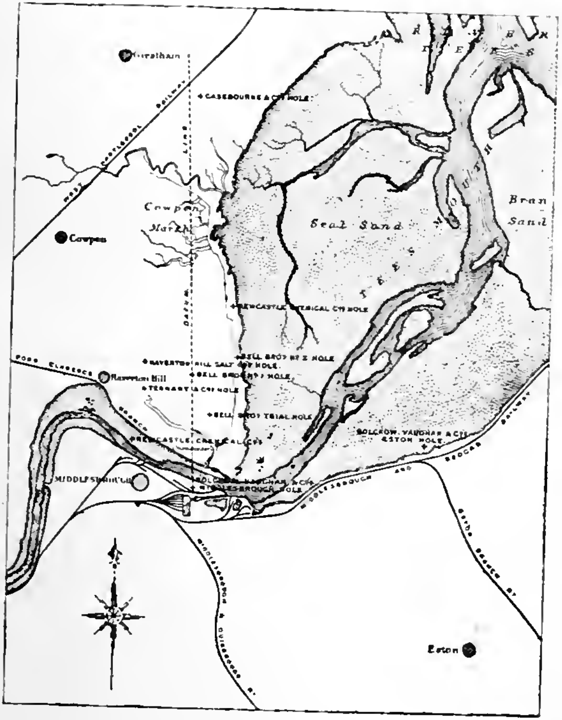
Deposition of well formed Crystals of Sulphur from a Solution of Calcium Polysulphide. E. Holderman. Chem. Zeit. **11**, 573.

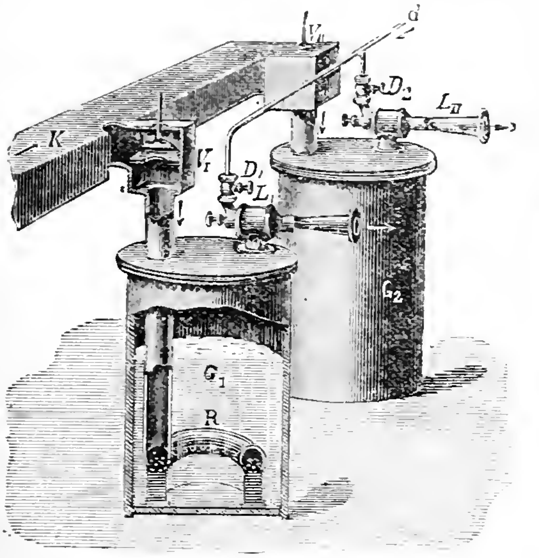
A SOLUTION of calcium polysulphide (obtained by boiling 1 part of CaO, 2 parts of S, and 20 parts of water), which had been kept in a stoppered bottle, occasionally opened, for seven years without apparent change, in the course of a few months deposited an abundant crop of well-formed crystals of sulphur. The solution was then found to contain calcium hyposulphite (CaS_2O_3), but no sulphide. The oxidation must have been produced by the air admitted when the bottle was opened.
—A. G. G.



concentrating a saturated alcoholic solution of [illegible]

Apparatus for Absorption of Sulphuric and Sulphurous Acids, and for the Manufacture of Copper Sulphate (Rossler's system). Chem. Zeit. **11**, 574.

THIS method is suitable for all cases in which, by solution of metals in hot sulphuric acid, gaseous mixtures are evolved containing SO_3 and SO_2 mixed with air. The lead-lined iron cylinder G_1 is half-filled with a saturated solution of $CuSO_4$, and precipitated copper is added. After opening the valve V_1, a stream of the mixed gases is drawn by means of the Körting's injector L_1, from the flue K, into the liquid through the perforated tube R. When all the copper has dissolved, the cylinder G_2 is set at work, whilst G_1 is allowed to cool and deposit the $CuSO_4$. By this treatment the whole of the SO_3 and the greater part of the SO_2 are removed from the gases.—A. G. G.



The Crystallisation of the Alkaline Hydrates from Alcoholic Solution. C. Göttig. J. Prakt. Chem. **35**, 1887, 560—566.

ON heating a fairly concentrated solution of caustic potash in 96·8 per cent. alcohol to 60—80°, very fine microscopic crystals separate on the solution cooling to 50°. Their composition is not constant. When dried they form a fine powder, which loses its water of crystallisation on heating, and absorbs carbonic acid readily from the air. When placed in contact with the water it moves about over the surface until dissolved similarly to the alkali metals. This behaviour is characteristic of most of the hydrates prepared by the author, and has not been observed in the case of the hydrates of the caustic alkalis already known. If a very concentrated solution of caustic potash, in hot 96·8 per cent. alcohol, be allowed to cool, large columnar shaped crystals having the composition $2KHO + 9H_2O$ separate. These melt at 40°, and lose the last traces of moisture only with great difficulty. The hydrate $2KHO + 5H_2O$ is obtained by concentrating a saturated alcoholic solution of potassium hydrate to about half its volume, when the boiling point of the solution rises to 95—116°. On allowing to cool fine needle-shaped crystals separate, which melt below 50°, and which on continued drying over sulphuric acid in vacuo lose $1\frac{1}{2}$ molecules of water—the hydrate $KHO + H_2O$ remaining. If the alcoholic solution be concentrated until the boiling point reaches 100°, only crystals having the approximate composition $2KHO + 3H_2O$ result. All these crystalline hydrates absorb carbonic acid from the air very readily, and the freshly prepared substances always contain varying amounts of CO_2. With the exception of the hydrate $2KHO + 3H_2O$ they all show the characteristic behaviour when placed upon water, as does the crystalline hydrate of sodium, $NaHO + 2H_2O$ (see this Journal, 1887, 508), also prepared by the author.—C. A. K.

Improvements in the Manufacture of Hydrates of Strontia and of Baryta. J. Mactear, London. Eng. Pat. 5170, April 14, 1886. 4d.

STRONTIUM (or barium) sulphate is mixed with a little more than its equivalent of sodium sulphate, and also with carbonaceous matter. The finely-divided mixture is heated in a furnace, until the sulphates are almost completely reduced to sulphides. The resulting mass is dissolved in hot water, when sodium sulphide at once acts on strontium sulphide, forming strontium hydrate and sodium hydrosulphide. The former is obtained by crystallisation, while the latter remains in the mother liquor, which is subsequently boiled down, and the residue used again in reducing another batch of strontium sulphate with carbonaceous matter. If, as in the usual process, solid strontium sulphide be treated with hot water, it is split up into hydrate and hydrosulphide, the hydrate crystallising out, while the hydrosulphide remains in the mother-liquor and forms a by-product of the process. It is now proposed to utilise this by-product by mixing it with a solution of sodium sulphide, obtaining as a result strontium hydrate and sodium hydrosulphide, which are separated by crystallisation.—S. H.

Improvements in Apparatus for effecting the Absorption of Gases by Liquids or Solids. E. Edwards, London. From G. Lunge, Zurich, and L. Rohrmann, Krauschwitz, Silesia. Eng. Pat. 10,037, August 5, 1886. 8d.

THE essential parts of this patent specification are contained in a communication to this Journal (see p. 584); also this Journal, 1887, 538.—S. H.

Improvements in the Manufacture of Sodium Sulphites. J. M. Collett, Gloucester. Eng. Pat. 11,518, Sept. 10, 1886. 4d.

DRY sodium hydrate is treated with sulphur dioxide until it is converted to sulphite or bisulphite.—S. H.

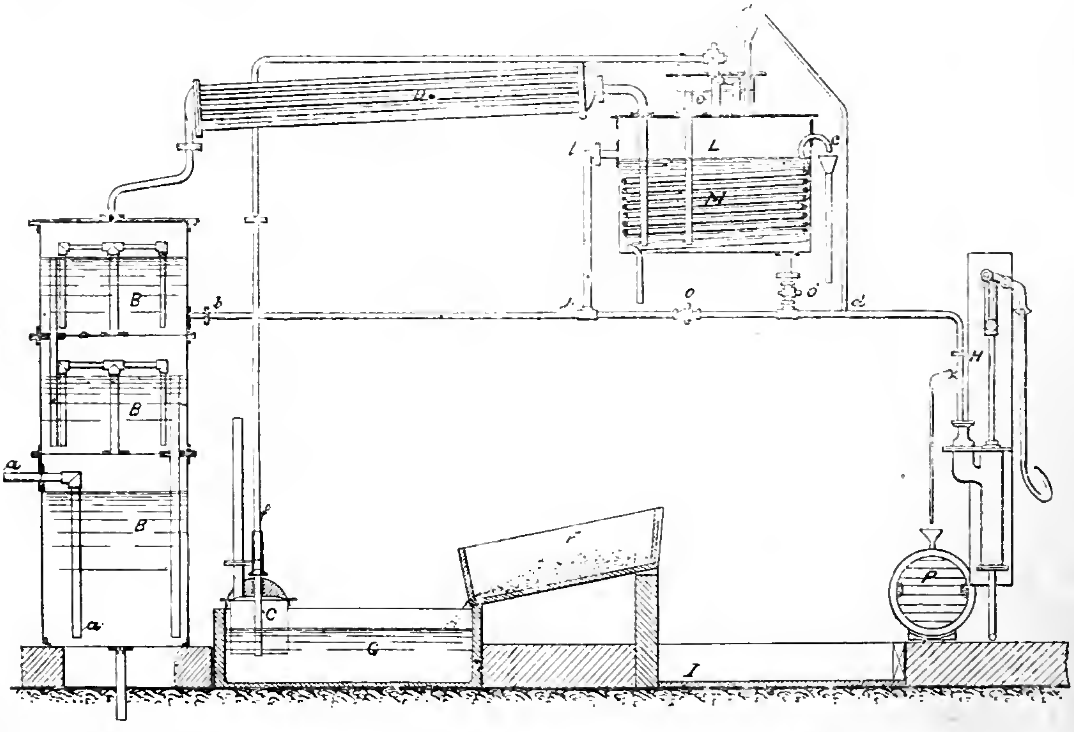
Improvements in the Treatment of Copper and Iron Pyrites for the Manufacture therefrom of Sulphuric Acid and Oxides of Copper and Iron, and in the Treatment of the said Oxides for the Production therefrom of Metallic Copper and the Higher Oxides of Iron. A. Brin, London, and L.Q. Brin, Paris, France. Eng. Pat. 12,070, Sept. 22, 1886. 8d.

THE pyrites is first mixed with fuel and ignited on a suitable hearth until the temperature is sufficient for the unaided combustion of the pyrites; air is then excluded, and a current of oxygen is introduced from beneath. The sulphur dioxide produced is drawn off by a steam jet, by which it is injected into a lead-lined chamber with water-cooled walls, provided with an inlet for a nitric acid spray, an escape pipe leading to condensers above, and a cock for drawing off the liquid products beneath, together with internal revolving beaters for the more complete mixture of the gases. The residue on the hearth in the case of copper pyrites is an oxide of copper which may be smelted for the metal; in the case of iron pyrites it is an oxide which may be submitted to the further action of oxygen for the production of pigments or other similar substances.—W. G. M.

Improvement in Apparatus for Distilling and Purifying Ammoniacal Liquids. L. A. Chevalet, Paris. Eng. Pat. 8819, July 6, 1886. 8d.

THE object of this invention is the production of a highly concentrated ammoniacal liquor, and this end is attained by condensing ammoniacal vapours freed from steam in ammoniacal liquor. The apparatus employed in this

process consists of a distilling chamber B, heated by steam and divided into three or four compartments, an air-cooler D and a condenser L. The ammoniacal liquid is pumped into the top of the distilling chamber B, and as it descends successively from one compartment to another it loses the volatile ammoniacal compounds until it reaches the last compartment of the still B, where it comes in contact with milk of lime, and is thus freed from the fixed ammoniacal salts. The vapours passing into the air-cooler become more concentrated inasmuch as the steam becomes partially condensed and returns to the still, while the ammonia proceeds to the closed reservoir L, which contains a cooling worm M. The reservoir L is two-thirds full of cold ammoniacal liquor, which absorbs the ammoniacal vapours bubbling through it: the worm A keeps the solution at a low temperature. The gases arising from L are first washed with ammoniacal liquor in the tank Q, and finally with sulphuric acid in the saturator G. If it be desired to manufacture ammonium sulphate, the liquor in L is allowed to become heated, when most of the ammonia will proceed to the tanks Q and G, which must be filled with sulphuric acid. By another modification this apparatus can produce solid ammonium carbonate. A tank is placed above L and connected with it by a wide pipe. A jet of cold water is directed against this upper tank, and the lower one L is allowed to heat slightly so as to distil ammonium carbonate. The latter condenses on the cold sides of the upper tank and forms a continually increasing crust. If the liquor obtained in the tank L is heated for a short time it gives off carbonic acid and sulphuretted hydrogen, while most of the ammonia remains in solution. Such a liquor is particularly suitable when cold for washing coal-gas and removing its carbonic acid and sulphuretted hydrogen.
—S. H.



Improvements in the Manufacture of Meta-stannic Acid, and in the Purification of Meta-stannic Acid. J. J. Hood and A.G. Salamon, London. Eng. Pat. 12,110, Sept. 23, 1886. 6d.

Metallic tin is treated with sulphuric acid, and the resulting mass, containing more or less stannous salt, oxidised with sodium nitrate. A large quantity of water is then added, to precipitate the meta-stannic acid, which, after being washed free from acid, and subsequently neutralised or rendered alkaline, is ready for use in the elimination of iron from aluminium sulphate or otherwise. The oxidation of the stannous salt may also be performed by ferric sulphate or manganese dioxide (Weldon mud). When industrially applied, the meta stannic acid gradually becomes so charged with iron as to interfere with the efficacy of its action, and the removal of the iron becomes imperative. To this end the stannic mud is boiled with sulphuric acid for a few minutes, a solution of stannous chloride added, in sufficient quantity to reduce ferric oxide to the ferrous state, and the latter is removed by washing. Any stannous chloride in excess is oxidised by bleaching powder solution. Organic matters are removed from the stannic mud by the combined action of sulphuric acid and an oxidising agent.—S. H.

Improvements in, or relating to, the Manufacture of Chlorate of Potash. J. W. Kynaston, Liverpool. Eng. Pat. 14,344, Nov. 6, 1886. 6d.

This invention has for its object the recovery of potassium chlorate and chloride from the mother-liquors, which are obtained as a waste product in the manufacture of potassium chlorate. For this purpose it is proposed to remove a large portion of the calcium chloride, which forms the principal constituent of the chlorate mother-liquors, by the addition of caustic lime. On heating, the latter combines with calcium chloride, forming calcium oxychloride, which crystallises out on cooling, and is a very stable compound when suspended in a solution of calcium chloride. Half of the latter is therefore only converted into oxychloride, while the other half remains in the mother liquors along with all the potassium chlorate and chloride. On evaporation these liquors yield crystals containing both potassium salts, which are separated in a well-known manner. The liquor drained off from these crystals is mixed with an equal bulk of fresh mother-liquor, and the treatment with lime repeated, as previously mentioned. The calcium oxychloride crystals are treated with boiling water, when the oxychloride is decomposed into calcium chloride and hydrate, which latter settles out. The superaatant liqnor is run away; the calcium hydrate washed with water is used again for the treatment of fresh mother-liquor.—S. H.

Improvements in the Production of Liquid or Compressed Chlorine. C. T. J. Vautin, St. Kilda, Victoria. Eng Pat. 8820, June 18, 1887. 4d.

CHLORINE GAS is collected in a receiver lined with a suitable material, which resists the action of the gas. When the receiver is full, it is connected with an air compressor, and air is forced in until the gas is compressed to any required degree or entirely liquefied. The liquefied gas may be distributed in suitably lined vessels for transport.—S. H.

Process and Apparatus for Automatically Mixing Liquids with Carbonic Acid. A. Brünler, Berlin, and C. G. Rommenhöller, Rotterdam. Eng. Pat. 9046, June 25, 1887. 6d.

THE object is attained by the utilisation of the power which is stored up in the compressed gas. The latter passes under great pressure through a jet injector, which aspirates the liquid to be impregnated with the gas, and both liquid and gas travel into a mixing tank, where a set of arms keeps up a continuous agitation. —S. H.

An Improved Process and Apparatus for the Production of Sulphuric Anhydride. E. Hänisch and M. Schröder, Neumühl-Hamborn, Germany. Eng. Pat. 9188, June 28, 1887. 6d.

THE object of this invention is to facilitate the combination of sulphurous acid and oxygen to form sulphuric anhydride. A mixture of the two gases in a certain fixed proportion is passed at a low, red heat, and under pressure, over asbestos, coated with spongy platinum, whereby a large surface and a lengthened duration of contact is ensured to the gases. The pressure also promotes chemical reaction by bringing nearer together the active gas molecules. A gas mixture consisting of 25% sulphurous and 75% air is most suitable for the process, and the mixing of the gases simultaneously with their compression is effected by a double cylinder compressor, the two cylinders of which have a cross sectional area in the proportion of 1 to 3. By these means the gas mixture will always have the most suitable composition, one cylinder pumping three times as much air as the other pumps sulphurous acid. The compressed gases mix in the conducting tube, whence they pass to the compressing vessel, and subsequently to the combining furnace. The latter is furnished with two wrought-iron pipes, heated to redness, and charged with platinised contact substance through which the mixed gases pass. Here the greater portion of the gases is converted into anhydride, whereas that which escapes passes into a tube beyond the furnace, through a valve and into a bent tube leading to condensing jars. To prevent deposition in these pipes they are surrounded with a steam-heated lead worm. Thus all this latter SO_3 is carried forward and condensed in the jars.—S. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Improvements in the Manufacture of Artificial Elaterite or Elastic Bitumen to be employed in Road Making, Roof Surfacing, and other like Purposes and Uses. W. Brierley, Halifax. From F. Wallbrecht and H. Russe, Hanover, Germany. Eng. Pat. 7492, June 4, 1886. 6d.

"THE Elaterite is found in its natural state principally in regions of volcanic origin, and forms a soft and elastic bitumen (mineral caoutchouc), formed under the influence of a high or volcanic temperature from the liquid bitumen or naphtha." It is proposed to manufacture this substance artificially by mixing the liquid bitumens or naphthas with vegetable oils or fatty or sebacic acids of vegetable origin, and heating this mixture under pressure with sulphur, compounds of sulphur, nitric acid, or other oxidising agent. The elaterite prepared in this manner may then be mixed with asphaltic substances and powdered limestone, and the mixture heated and ground. This powder can be pressed and stamped very easily. It resists friction and atmospheric influences, and compares favourably with the best native asphalte.—D. B.

X.—METALLURGY, Etc.

Improvements in the Manufacture of German Silver. E. Cottam, Sutton. Eng. Pat. 8989, July 9, 1886. 6d.

THE patentee claims the use of siliceous copper, made by heating shot copper for from three to six hours to a temperature just short of fusion, with a mixture of equal parts of sand and charcoal. An alloy of equal quantities of copper and nickel and a similar alloy of copper and zinc (brass) are also prepared. The siliceous copper and the copper nickel, with copper, iron, cobalt oxide, and charcoal, are melted together, and then before pouring, brass and tin are added. The following percentage proportions are recommended :—Siliceous copper 18, copper-nickel 28½, copper 4¼, iron 2¾, brass 46, cobalt oxide ¼, tin ¼.—W. G. M.

An Improved Process and Apparatus for obtaining Spelter and Caustic Soda, Chloride of Lime, Chloride of Calcium, or other Products. P. Higgs, London. Eng. Pat. 9158, July 14, 1886. 8d.

THE zinc ore, rendered conducting by admixture with graphitic coke, serves as the anode, while plates of some conducting material form the cathode, and receive a deposit of metallic zinc. The electrolyte consists of a solution of chloride of magnesium or sodium chloride ; in the latter case the products consist of zinc, sodic hydrate, and chlorine. The chlorine enters at the bottom of a tower, from the top of which lime is falling in a state of fine powder ; by this means oxychloride of lime is formed, and from it chloride of calcium can be obtained by the application of heat.—B. T.

Improvements in Apparatus used for Coating Sheets of Iron and Steel and Articles of Iron and Steel with Zinc or Alloys of Zinc, or other Coating Metal or Alloy. R. Heathfield, Birmingham. Eng. Pat. 10,089, Aug 6, 1886. 6d.

As the plate leaves the bath of zinc it is passed between one or more pairs of flat or slightly curved brushes, pressed with an even pressure against it, and having, if desired, a reciprocating motion.—W. G. M.

Improvements in Furnaces for Chlorinating Ores and in the Process connected therewith. J. E. Baugh and C. Hinksman, London. Eng. Pat. 11,776, Sept. 16, 1886. 8d.

THE furnace is of a kiln form, and made of such a size that 20 to 100 tons may be treated at a time. After preparing a simple foundation and rearing the outside walls for any required internal size in length, width, or height, a number of small arches is built across, leaving sufficient space beneath for firing ; these arches are crossed every 30in. by 2in. openings. Pyrites in lumps is laid over the 2in. openings, forming a column of about 10in. in width and 1ft. in height the whole length of the furnace, which, for operating on 20 tons, is about 12ft. square within and 14ft. high. Pulverised calcined ore mixed with salt in the ordinary manner is now placed between the rock pyrites on the arches. The columns of rock pyrites, first broken to any required lump size, are again reared a foot higher, when more prepared fine ore for chlorination is added as before, and this repeated until the furnace is charged. After the use of a little fuel to kindle the sulphur in the raw pyrites, the furnace may be left undisturbed, without cost of material or labour of any kind, until the charge is calcined and has cooled down ready to be withdrawn. "The rock pyrites is then passed to the crusher for pulverisation, to be afterwards mixed with salt or any other chlorinising agent, when the already chlorinised ore will be found completely prepared for any of the humid process." A chimney, 8–10ft. in height, built on the top of the kiln or furnace, will be sufficient where no objection is made to noxious vapours. When gold is contained in the ore in the form of arsenide or sulphide, it is found to be converted into chloride, along with the silver and copper present. A large percentage of the metallic gold, if not the whole of it, is also converted into chloride. When, however, it is found by assay that metallic gold is still present, chlorine generated in the ordinary manner is passed through the ore after the latter has been leached by the aid of boiling brine. The gold, silver, and copper are precipitated together by means of metallic iron.—J. T.

Improvements in obtaining Gold, Silver, and other Noble Metals from Ores or other Compounds. J. S. MacArthur, Pollokshields; and R. W. Forrest, W. Forrest, and G. Morton, Glasgow. Eng. Pat. 11,817, Sept. 17, 1886. 6d.

The crushed ore is submitted, in suitable tanks, to the action of a solution, saturated with chlorine, bromine, or iodine, of a substance which, unacted upon by halogens, is itself incapable of precipitating gold from solution, but which will prevent the solution of base metals. Borax, sodium hypochlorite, and many other bodies are specified as suitable for the purpose. The gold and silver are precipitated from the decanted liquors, into which they have dissolved as haloid salts, and the halogen is recovered for further use.—W. G. M.

Purification of Iron Ore and Fluid Iron Metal, and Apparatus therefor. B. H. Thwaite, Liverpool. Eng. Pat. 11,972, Sept. 21, 1886. 8d.

Molten pig iron in a falling stream is subjected to the action of one or more jets of air, by which it is partially oxidised, and so purified. Several more or less elaborate pieces of apparatus are shown with this object in view. Iron ores are purified by being passed through a "calcining revolving cylinder," having its axis somewhat inclined to the horizontal. In this cylinder the ore is subjected to reducing gases, and drops out of the lower end "in the form of reduced spongy metal into a fine B.W.G. riddle, by which the metal and its impurities are properly shaken, and the finer particles of the metal and earthy and other impurities fall into a trough in which there revolves a magnetised Archimedean screw, to which the finer metal particles become attached by magnetic attraction; the earthy particles fall through the perforations." The present invention principally consists in improvements on a prior invention (Eng. Pat. 11,402, Sept. 25, 1885; this Journal, 1885, 615; 1886, 461).

Improvements in Producing Silicous Copper and utilising the same for Metallurgical Purposes. C. Heusler, Bonn, Prussia. Eng. Pat. 12,720, Oct. 6, 1886. 6d.

The inventor fuses copper with siliceous pig iron, removes the two upper layers which form on allowing the molten mass to stand, and utilises the copper silicide left at the bottom of the vessel for refining purposes or for producing silicon alloys.—O. H.

Improvements in obtaining Zinc from its Blende or Sulphide. R. Hannan and M. Milburn, Glasgow. Eng. Pat. 5029, April 5, 1887. 6d.

An upright retort, with bell and cone hopper above, with tap holes beneath, and condensing arrangement suitably placed, is used in preference. The charge consists of zinc sulphides, mixed with an equivalent quantity of metallic (malleable) iron scrap, or with iron oxide and carbon, and with the necessary fluxes. This is fed in through the hopper, the liberated zinc is collected in the condenser, and the resulting iron sulphide and slag are tapped off at intervals. The arrangement is thus continuous. Copper, if present, forms a regulus, and may be extracted by wet processes; lead, silver, and gold sink to the bottom in the metallic condition.

—W. G. M.

Process and Apparatus for Extracting the Tin from Tinned Iron Cuttings or Scrap, and from Metal covered with Tin. S. T. Montagne, Nantes, France. Eng. Pat. 6370, May 2, 1887. 6d.

This is an improvement on Eng. Pat. 2865, of 1886 (this Journal, 1887, 294). The scrap is packed loosely in a number of chambers arranged in series, so that a current of hydrochloric acid gas introduced into any one flows successively through each of the others, the waste gases escaping finally into a flue. When the scrap in the first chamber is sufficiently treated, it is washed with water spray and afterwards steam; the tin liquors are then drawn off into a reservoir, the charge withdrawn, and a fresh quantity introduced. This chamber is then made the last of the series, that which was formerly second now receiving the fresh acid gas, and so on.—W. G. M.

A Process of obtaining Aluminium from its Ores or from Aluminiferous Earths, or Earths containing Alumina, and of combining Aluminium with other Metals. W. A. Baldwin, Chicago, U.S.A. Eng. Pat. 7198, May 17, 1887. 6d.

A mixture of 4 parts of clay, 1 part of charcoal, and 3 parts of sodium chloride fused in a suitable pot yields a light alloy of aluminium and sodium, to be skimmed off and remelted in a fresh crucible under a cover of sodium or sodium chloride; when melted, the contents of the second vessel are poured into a heated mould, wherein the heavier aluminium subsides. Or by introducing other metals, useful alloys are formed without fusion, by the simple permeation of the alloying metal by the aluminium.—W. G. M.

Improvements in Treatment of Ores. J. Belon, Paris, France. Eng. Pat. 7519, May 25, 1887. 8d.

It is proposed to treat ores in general, and more especially pyritous, auriferous, and argentiferous ores, with pure hydrogen or gaseous hydrocarbons, for the purpose of extracting their metals, instead of employing carbon and the oxygen of the air. In some cases, retorts may be employed, which are heated externally and are charged with the ore and reducing gas or gases. In other cases, blast furnaces may be employed, into which the reducing gases are blown, and also the necessary amount of atmospheric air or of pure oxygen to heat the charge. No claim is made to any of the apparatus described.—J. T.

An Improved Method of and Apparatus for Reducing Zinc Ores and Collecting the Metallic Zinc therefrom. E. Walsh, St. Louis, U.S.A. Eng. Pat. 8599, June 15, 1887. 8d.

Zinc oxide reduces at 1300° F., and the metal volatilises at about 100° F. lower than that temperature. At 1300° F., carbon is unaffected by the action of carbonic acid, and the carbonic acid generated from the reduction of the zinc oxide is carried off with the zinc vapour at that temperature. Carbonic acid at a temperature below 1300° F., when mixed with zinc vapour, oxidises the latter; but when zinc vapour and carbonic acid, both at a temperature of 1400–1500° F., are allowed to pass through carbonaceous matter at the same temperature, the carbonic acid is immediately converted into carbonic oxide, and the zinc vapour remains unoxidised. Applying these principles, it is proposed to reduce zinc oxide in a closed top cupola. The cupola is charged with a mixture of fuel and zinc oxide, by means of a hopper which descends below the level at which the surface of the fuel is maintained by means of two more hoppers, through which fuel alone is charged. Care is taken that the ore hopper descends to a point in the furnace at which the temperature is 1500° F., or slightly higher. The hoppers have each a movable cover and a conical valve to prevent escape of gases during charging. The zinc vapour and products of combustion are taken off above the fuel to a condenser, consisting of two horizontal iron pipes placed parallel to each other and connected together by a series of U-shaped pipes placed vertically above them; the whole being heated to a temperature of 780—1200° F., so that the zinc is collected and maintained in a liquid state. The waste furnace gases are either passed into heating flues surrounding the condenser, or are otherwise utilised. In a modified form of the cupola, one charging hopper only is used, which does not pass below the level of the fuel, through which both ore and fuel are charged; and the reduced zinc, together with the products of combustion, are drawn off to the condenser from a point below the surface of the fuel at which the temperature exceeds 1400° F.—J. T.

XII.—PAINTS, VARNISHES AND RESINS.

Improvements in the Manufacture of White Pigment. F. M. Lyte, Putney. Eng. Pat. 10,298, Aug. 11, 1886. 6d.

The covering power of insoluble or sparingly soluble lead-salts (*e.g.*, carbonate, sulphate, chloride and phosphate) depends in part on the degree of their basicity. The patentee prepares these basic salts by digesting insoluble or difficultly soluble normal or partly basic lead-salts with solutions of soluble basic lead-salts, such as basic lead-acetate.—F. W. T. K.

Improvements in the Preparation of Colours for Artistic Purposes. Alexander M'Lean, Brockley, and Robert Smith, London. Eng. Pat. 11,493, Sept. 9, 1886. 6d.

According to the patentees, the bleaching of aniline colours is due to oxidation. By the employment, however, of materials containing little or no oxygen (*e.g.*, fusel oil, benzene, pitch, resins, etc.), they prepare coloured varnishes with aniline colours, in which the latter remain perfectly unaffected by the strongest light. They have obtained good results with the following mixture, to which the requisite quantity of "aniline crystals" is added: Fusel oil, 37·02; alcohol, 24·68; Swedish pitch, asphaltum or tar, 10·00; resin or gum (gum Dammar), 28·30.—F. W. T. K.

Improvements in Preservative Coatings for Ships' Bottoms. J. B. Hannay, Loch Long. Eng. Pat. 12,499, Oct. 2, 1886. 6d.

The coating consists of a mixture of powdered zinc, mercuric and other metallic oxides and a suitable coating medium. According to the patentee, the use of mercuric oxide increases the efficiency of the coating as a preservative against shellfish, on account of the formation of metallic mercury through the reduction of the oxide by the zinc; and also the anti-corrosive action is due to the zinc in the coating placing the metal of the ships' bottoms in an electro-negative state.—F. W. T. K.

A Process of and Apparatus for obtaining Purified Carbon from Soot and other similar Carbonaceous Products of Combustion. R. Pringle, Blackheath. Eng. Pat. 11,684, Sept. 14, 1886. 8d.

The soot, etc., is worked into a thin paste, strained to remove coarser particles, and then passed down a tube into a vessel almost full of water. The mixture enters the lower vessel (under a pressure due to a head of ten feet) by a nozzle or rose fixed at the bottom of the vessel and directed upwards. Four inches above the nozzle is fixed a horizontal plate, against which the jet of mixed soot and water strikes. As soon as the current is thus arrested, the carbonaceous matter separates from the accompanying impurities, the latter sinking to the bottom, the former rising to the surface of the liquid in the vessel, where it is skimmed off. To prevent the carbon being carried away by the overflow water, a dip curtain is placed in front of the outlet at the top, and the carbon is held back whilst the water flows off. The process can thus be worked continuously.

—F. W. T. K.

XIII.—TANNING, LEATHER, GLUE AND SIZE.

An Improved Method of making Leather and other Materials Flexible to any Degree, and of Waterproofing the same. T. Laycock, Northampton. Eng. Pat. 9613, July 26, 1886. 4d.

The patentee employs wax of various kinds, such as paraffin, bees', common, or earth wax alone or mixed with "petroleum jelly," and drying oils. The ingredients are heated in a suitable vessel to about 200° F. and the leather is soaked in the melted wax. The leather when impregnated is placed in a drying chamber. If flexibility is not required, paraffin wax alone, or 9 parts of paraffin wax with 1 part of common earth wax, are used. If greater flexibility is required, 4 parts of paraffin to 1 part of common earth wax, or 1 part of petroleum jelly are used.—B. H.

A Process for clearing Hides, Skins, Hair, Wool, or Fur from Lime. E. P. Nesbit, Wandsworth. Eng. Pat. 12,681, Oct. 5, 1886. 4d.

In the inventor's specification, No. 7744, of 1886 (this Journal, 1887, 513), was described a method of removing lime from hides or skins, preparatory to tanning, by subjecting them, while in water, to the action of carbonic acid gas. The present invention consists in the application of this method to the removal of lime from hides, or scraps of these, such as are used for the manufacture of size or glue, and also from hair, wool, or fur which has undergone lime treatment.—B. H.

XIV.—AGRICULTURE, MANURES, Etc.

On the Probable Part played by Magnesia and other Elements in resisting Phylloxera in French and American Vines. A. C. Dejardin. Compt. Rend. **104**, 1249.

The author draws the following conclusions from his investigations:—(1) That in places where French vines offer the greatest resistance to phylloxera, and American vines flourish the best, magnesia plays an important part as a constituent of the soil. (2) The percentage of magnesia in the ash of American vines is somewhat greater than in that of the Vinifera. (3) In rare cases where the resistance of French vines against phylloxera has been increased, a greater amount of magnesia has always been taken up by the plants. Nitrogen, iron, manganese, and especially phosphoric acid, also increase the resistance offered to phylloxera; and the author suggests the addition of ammonium magnesium phosphate to manure, and the use of manures containing nitrogen, iron, manganese, phosphoric acid, and magnesia, as a preventive against this vine pest.—C. A. K.

Are Nitrates formed in the Organism of Higher Plants? E. Schulze. Ber. **20**, 1500—1504.

Kreusler (*Ber.* **20**, 999) has shown that young potato plants, sown in sawdust and watered with a tertiliser free from nitrogen, contain no nitrates. On the other hand the author had previously found (*J. Prakt. Chem.* [2], **32**, 451) that the young shoots of lupines and pumpkins grown in pure sand, and watered with distilled water only, contain considerable quantities of nitrates. This at first sight seems to be evidence in favour of the occurrence of nitrate-formation within the organism as assumed by Berthelot and André. When, however, the seeds are sown upon paraffined gauze lying on the surface of distilled water, no nitrates could be detected. Upon further investigation the author came to the conclusion that the nitrates contained in the shoots when grown in sand are absorbed from the sand, where they are produced, by oxidation of nitrogenous matter given off by the plants.—A. G. G.

The Origin of Methyl Alcohol in Plants. H. Gutzeit.

Chem. Zeit. **11**, 663.

According to Thoms (*Pharm. Centralhalle*, 28, 231) the presence of methyl alcohol in plants is due to the decomposition of a salt of methylamine by means of alkali. This, the author disputes, since in the first place amines cannot be thus decomposed by alkalis, and further, were such a decomposition possible in plants, then one would, in all probability, be able to detect methylamine wherever methyl alcohol is found, and this is contrary to the experiments of Moslinger Maquenne and the author, ammonia being present in quantity, but only traces of the compound ammonias. Thoms found the reverse the case with *Acorus calamus*, the chloride of the volatile base contained in the root consisting essentially of methylamine hydrochloride, and containing only traces of ammonium chloride. Since, however, the former was dissolved out by means of a mixture of absolute alcohol and absolute ether, in which ammonium chloride is not altogether insoluble, and further, because the chlorine determination was effected by igniting the dried chloride with calcium carbonate, and then precipitating with silver solution after exhausting the ignited mass with nitric acid, the author considers the results, which are contrary to his own, to be incorrect.—C. A. K.

XV.—SUGAR, GUMS, STARCHES, Etc.

A New Galactan and some Properties of Galactose.

E. O. von Lippmann. Ber. **20**, 1001—1008.

The author has succeeded in isolating a new substance, which he calls γ-*Galactan*, from the liquors from the lime mud forming the end product in the purification of sugar. It closely resembles dextran and levulan in appearance, and when pure consists of a white amorphous substance, which, in the hydrated state, is easily soluble in hot and cold water; in the anhydrous state it is soluble in hot, but only very slowly in cold water: the hot solution does not gelatinise on cooling, resembling, in this respect, dextran, and differing from levulan. The substance is insoluble in alcohol. It has the composition $C_6H_{10}O_5$, and has $\alpha_D = +238°$, a number more than three times as high as that for cane sugar; it does not reduce Fehling's solution, and gives mucic acid on oxidation with nitric acid. When inverted with dilute sulphuric acid, it is completely converted into galactose. The substance appears to belong to the series of bodies lately found in the vegetable kingdom by the author and others, which yield galactose on invertion. The galactose from the above γ-galactan was obtained in crystalline masses, which melted at 166—168°; the optical activity was $\alpha_D = +81{\cdot}5$; when oxidised, it yielded 77 per cent. of mucic acid; it also combined with phenylhydrazine.

In conclusion the author discusses the fermentability or otherwise of galactose, and considers that further experiments are necessary, in order to explain the present discordant views.—G. H. M.

On Progress in the Manufacture of Starch, Dextrose and Glucose. Prof. L. V. Wagner. Dingl. Polyt. J. **264**, 174—179.

Leon Cuisinier, in Paris, has patented a process for the saccharification of starchy substances by means of a malt which has been allowed to germinate for from 7 to 10 days. The raw materials must be made perfectly neutral (acid free) by treatment with a 1 per cent. soda, or ½ per cent. sulphuric acid solution, as the case may be. The grain after two or three days' soaking in tepid water, should contain not more than 40—45 per cent. water, and is then to be ground. The moist materials are made into a paste with an equal weight of water, and from 2½ to 5 per cent. of malt is well kneaded into it, during an hour. The liquefaction of this paste takes place in an upright cylinder, surrounded by a water-bath which is maintained at 75° C., and provided with powerful stirring gear. The mash thus obtained is then heated in a steam jacket, under a pressure of one atmosphere for about an hour, then cooled to 70° and treated with 1 to 2 per cent. of malt infusion. After two hours the solution is put through a filter-press, cooled to 50°, and treated with 15 to 20 per cent. of malt infusion, which is added in 5 per cent. lots every two hours. When thoroughly saccharified, the solution is heated again, filtered and evaporated to 40° Bé., and sold as concentrated beer wort.

Joseph Franklin Gent, of Columbus, Ind., U.S.A., frees maize from the germs and husks by steaming at 160° in a special apparatus, for not longer than 1 minute, and subsequently crushing and sifting the grain. The product thus obtained is then again steamed, pressed into thin cakes, and brought into the market under the name of "Cercaline."

Messrs. Vierneisel, K. Trobach, and Alfred Cards recommend the following treatment of potatoes for the purpose of dextrose manufacture, avoiding thereby the necessity for the separation of the starch from the pulp, which always retains a considerable percentage, and utilising the roots at the period when they contain most starch—viz., at their harvest time; thus avoiding also the loss of starch which stored potatoes always undergo. The potatoes are washed and ground, the paste put through a filter-press, in which the cakes are well washed with a solution of calcium bisulphite, to prevent any fermentation, and then either dried for storing or worked up forthwith. The cakes made into a suitable paste with water, are saccharified under pressure, by acid; the acid sugar solution is thereupon neutralised with calcic sulphite and chalk, put through a filter-press, evaporated to 30° B., again filter-pressed, and finally concentrated at 100° down to 35° B., for crystallisation. The resulting sugar when separated from the molasses is ready for the usual processes of recrystallisation. Thadeus v. Korvins-Sákovicz and David Rosenblum, of Warsaw, produce crystallised grape sugar, from all sorts of starch, by boiling 10 per cent. solutions of starch with certain quantities of sulphuric anhydride, which quantities vary from 4·9 per cent. with 11 hours' boiling when working in open vessels, to 0·15 per cent. when the operation is conducted in a closed vessel, and under a pressure of four atmospheres. The boiling in the first case lasts eleven hours, in the latter only four hours. Instead of using charcoal to decolourise the neutral sugar solution, it is cooled to 45° and about 0·2 per cent. (on the weight of starch) of permanganate of potash added, whereby a brown precipitate is formed, the solution after passing through the filter-press being perfectly colourless. The crystallisation is performed under vacuum, but the crystals cannot be readily freed from the mother-liquor.

Alf. Seyberlich, of Riga, and Alex. Trampedach, of Mitau, transform starch into sugar by the action of dilute nitric acid. The starch is made into a milk with water, and run into a dilute boiling solution of nitric acid, and boiled until 10 drops of the solution added to 200cc. 96 per cent. alcohol no longer produce any turbidity. The proportions used are 1000 starch, 5 nitric acid, and 2000 to 3000 water. They then recommend that the solution be made distinctly alkaline by the addition of sodium or potassium carbonate, thereupon evaporated in the vacuum apparatus to 35—36° Bé., and allowed to crystallise. The crystals thus obtained are well developed, and easily separated from the mother-liquor.—T. L. B.

Manufacture of Carbonic Acid in Sugar Works.

Dingl. Polyt. J. **264**, 191—192.

Nearly half the Russian sugar-works obtain their carbonic acid from the flue gases, which, however, usually contain only 8 to 12 per cent. Jelinck obtains a richer gas by utilising the gases of only one boiler, the damper being kept as closely shut down as possible, and the gases removed by a pump the supply pipe to which is adapted in *front* of the damper. Under most favourable conditions 18 per cent. of carbonic acid in the gas are obtained, sufficient to work up from 160,000 to 170,000 kilos. roots.

P. Ehrhardt describes in *Deutschen Zuckerindustrie*, 1887, 78, a continuous apparatus, consisting of a blast furnace, as is used in French factories, into which limestone and fuel are together thrown, in the proportion of 7 parts limestone to 1 of coke. The heat is very thoroughly used up, and the gases are drawn off at a lower temperature, and contain on an average 30 per cent. CO_2. Another apparatus consists of a so-called step-kiln, in which the warming, burning, and cooling chambers are kept distinct, but owing to the fact that the material has to pass through two elbow-shaped and one level channel, it will probably be found difficult to keep in regular work.—T. L. B.

The Sweetness of Grape Sugar. Chem. Zeit. **11**, 139.

According to numerous experiments made with different persons, Herzfeld concludes that 153 parts of glucose are equivalent to 100 parts of cane sugar—*i.e.*, that the relative sweetness of these two kinds of sugar is approximately in the proportion of $\frac{2}{3}$: 1.—D. E. J.

Errata.—On p. 553, second column, line 2 from bottom, for "Madgeburg," *read* "Magdeburg." On same page and column, line 25 from bottom, *for* "acetic acid," *read* "acetic and lactic acids."

XVI.—BREWING, WINES, SPIRITS, Etc.

The Influence of the Mineral Constituents of Water upon the Composition of Worts. E. R. Moritz. Dingl. Polyt. J. **264**, 338—339.

The author's results are given in the following table, from which it will be seen that common salt added to the mash liquor increased the yield of maltose and dextrose by 9 per cent. He therefore recommends the addition of 20 to 35grms. of salt per hectolitre of water before mashing:—

Mash Water.	Maltose per cent.	Dextrose per cent.	Total per cent.	Colour of the Wort.
1. Distilled water	18·96	18·01	66·97	Pale.
2. New river water..........	48·96	18·01	66·97	,,
Distilled water containing				
3. 50·37 salt per hectolitre ..	50·18	25·77	75·97	Extremely pale.
4. 34·70 calcium chloride	46·68	15·10	61·78	Very pale.
5. 10·10 gypsum	47·79	17·34	65·13	,,
6. 36·34 magnesium sulphate	47·79	17·31	65·13	,,
7. 16·07 sodium sulphate	48·96	18·01	66·97	Rather darker,
8. 11·80 sodium nitrate	48·96	18·01	66·97	,,
9. 11·27 sodium carbonate ..	42·71	20·45	63·16	Dark.
10. Burtonised water	49·57	15·66	65·23	Very pale.

—T. L. B.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(*A*) CHEMISTRY OF FOODS.

The Relation of the Yield of Butter to the Acidity of the Cream. J. Sebelien. Chem. Zeit. **11**, 133.

From a series of experiments made, the greater the acidity of the cream used, the greater the yield of butter appears to be. The amount of fat contained in butter milk decreases, as the degree of acidity of the cream increases up to an acidity equal to 40cc. decinormal soda, when the decrease ceases. In some experiments the fat seemed to increase above this limit. The author determines the degree of acidity of the cream by titrating 50cc. with decinormal caustic soda solution until a drop of an alcoholic solution of phenolphthaleïn acquires a red tint as it spreads over the surface of the cream. The time necessary for churning increases regularly with an increase in the acidity of the cream.—C. A. K.

Examination of Butter with the Margarimeter. F. Benecke. Zeits. f. Nahrungsmittel-Untersuch. u. Hygiene, 1887, 87.

The application of the margarimeter rests on the supposition that butter has a higher specific gravity at 100 than all other animal and vegetable fats (this Journal, 1887, 447). A specific gravity of 0·8650—0·8670 at 100° is taken as a sign of the purity of butter, but the author has found that the specific gravity of ground-nut oil is 0·8630, that of sesame oil 0·8675, and that of poppy seed oil 0·8710, all taken at 100°. Still the margarimeter is of use as a preliminary test, the specific gravity of four adulterated samples of butter examined being from 0·8610 to 0·8625.—C. A. K.

Variations in the Amount of Phosphoric Acid contained in Milk. A. Andouard. Compt. Rend. **104**, 1298.

The author draws the following conclusions from his results:—1. The phosphoric acid in milk decreases from the beginning to the end of lactation, while the amount of butter, and especially of sugar, is also decreased during the same period. 2. With two of four cows experimented on the quantity of caseïn increased: with the other two it decreased. 3. The increase of solids in milk during lactation is not constant. 4. The age of cows appears to influence the quantity of milk given, the youngest giving the least. The nutritive power of the food affects both the quality and the quantity of the milk. 6. In opposition to Kröner's conclusion, the author states that green fodder is better for cows than dry fodder. Cabbages and leguminous plants are the best green fodder, and then in order of merit potatoes, beetroot and maize. 7. Individuality appears the chief factor in modifying the quantity and composition of the milk.—C. A. K.

(*B*) SANITARY CHEMISTRY.

Examination of Effluent Water. H. Schreib. Rep. Anal. Chem. **7**, 271—275.

The author has endeavoured to account for the remarkable fact that effluent water often contains more organic matter in solution after than previous to being purified. To a certain extent this may be traced to the lime which has been added, and which renders soluble certain bodies previously suspended in the water. But this cannot be the only cause. Attention is particularly drawn to the fact that waste water which has not been purified decomposes very rapidly, which entails loss of organic matter, whereas lime, etc., preserves the water by stopping the fermentation. Effluent water containing large quantities of carbo-hydrates is particularly liable to decomposition.—A. R.

Composition of the Water of the River Bode as Influenced by Drainage from the Potash Works, "Douglashall." H. Focke. Rep. Anal. Chem. **7**, 287.

On Ptomaines from Pure Cultures of Vibrio Proteus. O. Boeklisch. Ber. **20**, 1441—1446.

It has been repeatedly observed that animals injected with the vibrio proteus of Finkler and Prior (which occurs normally in the intestinal canal), often exhibit pathological symptoms which sometimes end in death. In order to determine whether this microbe produces a specific poison by its action upon proteids, the author has submitted sterilised beef broth to the action of pure cultivations, at a temperature of 37° to 38° for several weeks. The only bases produced were ammonia and the non-poisonous cadaverine (pentamethylenediamine), together with traces of indole. As it appeared likely that the pathological appearances observed in animals might have been due to the impure cultivations of the vibrio, the experiments were repeated with the addition of certain putrefactive bacteria. It was now found that the action of the vibrio was entirely altered, the products containing, in place of the innocuous cadaverine, the highly poisonous methylguanidine.—A. G. G.

XVIII.—ELECTRO-CHEMISTRY.

Note on a New Class of Voltaic Combinations in which Oxidisable Metals are replaced by alterable Solutions. C. R. Alder Wright and C. Thompson. J. Chem. Soc., 1887, 672—676.

The authors find that voltaic combinations can be obtained by substituting for oxidisable metals plates of platinum or other incorrodible material immersed in liquids capable of taking up oxygen or chlorine, and opposed to similar plates immersed in fluids capable of yielding up oxygen or chlorine, the two plates being connected by a siphon or a wick, or arranged as in a gravity cell. As an illustration, a solution of sodium sulphite is opposed to potassium permanganate, the former being oxidised to sulphate while the latter is reduced.—O. H.

Improvements in the Construction of Secondary Batteries. J. S. Sellon, London. Eng. Pat. 5631, Dec. 23, 1881. 4d. (Third Edition.)

Plates or supports, composed of materials such as carbon or platinum, not readily subject to oxidation or other destructive action, are made use of, and may be made of a cellular, corrugated or fluted shape: or a compound plate composed of two outer non-metallic plates, with an intervening plate of platinum, may be utilised. —B. T.

New or Improved Treatment or Manufacture of Materials for Use as the Incandescing Medium or Luminant of Electric Lamps, or for other Purposes. T. Mace, New York, U.S.A. From the Vitrite and Luminoid Co., New York, U.S.A. Eng. Pat. 9696, July 27, 1886. 6d.

This treatment, as applied to carbon filaments, for example, is as follows:—The filament is dipped in a solution of an organic salt of aluminium (such as the methylate or ethylate), after which an electric current is passed through it in the absence of oxygen. The decomposition of the salt thus effected causes a deposit of carbon and alumina to form upon the filament, which confers upon it a high degree of strength and elasticity, and enables it subsequently to resist disintegration by the electric current.—A. R. D.

Improvements in Secondary Batteries. T. J. Jones and W. H. Tasker, London. Eng. Pat. 11,101, Aug. 31, 1886. 8d.

A thin sheet of lead is perforated with oblong holes, surrounded by two thin sheets of celluloid and corrugated or crimped by suitable means, the bends being parallel to the intervening strips of lead. The lead strips are thus separated by distances equal to the double thickness of celluloid, and these spaces are filled with a paste formed of lead monoxide and ammonium sulphate solution. Several modifications of this method are described.—B. T.

An Improved Arrangement of Electric Battery with means for regulating the amount of Submersion or Withdrawal of the Positive Plates. H. Carter, London. Eng. Pat. 11,239, Sept. 3, 1886. 8d.

The carbons are attached to the sides of very elongated cells, but do not extend to the bottom. The zincs are carried on a suitable platform with sliding bars, which can be adjusted by a set screw until the required surface of the positive plates is immersed in the solution. A combined binding screw and switch is described.—B. T.

Improved Means for effecting the Electro-chemical Generation of Chlorine in Metallurgical Operations for the Extraction of Gold from its Ores, and for other Purposes. D. G. Fitzgerald, London. Eng. Pat. 11,242, Sept. 4, 1886. 8d.

The inventor makes use of peroxide of lead as the anode, and builds up this anode with slabs or plates of the peroxide, cemented together with a paste of litharge and dilute sulphuric acid. The anodes hitherto used have been unable to withstand the action of nascent chlorine. —B. T.

Improvements in and Apparatus or Means for Electroplating. R. K. Boyle, London. Eng. Pat. 11,291, Sept. 4, 1886. 8d.

This is a dry process of electro-plating, and by its means plating of iridium can be effected, and plating of aluminium facilitated. The article to be plated and the metal to form the plating are included in an electric circuit, and a rapid make and break is produced between the article and metal, the article being gradually moved along to expose new surface for deposition.—B. T.

Improvements in the Manufacture of Positive Pole-plates for Secondary Batteries or Accumulators. S. Farbaky and S. Schenek, Schemnitz, Hungary. Eng. Pat. 11,487, Sept. 9, 1886. 8d.

The active material is packed in polygonal divisions of a leaden grating, having unoccupied spaces between these divisions, so as to allow of the expansion of the active material without alteration to the form of the plate. —B. T.

An Improved Primary Battery. C. E. O'Keenan, Paris, France. Eng. Pat. 11,834, Sept. 17, 1886. 11d.

A distributing canal, in connection with the cells and also with vessels containing crystals of the salts used, is adopted to maintain the solutions at their proper level; while by means of an automatic arrangement desaturating solutions are supplied to the cells. An apparatus for measuring the number of ampère-hours given out is attached.—B. T.

A Method of Producing Carbon Fibres or Filaments. W. Maxwell, London. Eng. Pat. 11,997, Sept. 21, 1886. 6d.

WITHIN a closed vessel kept constantly full of a gaseous hydrocarbon, under a pressure preferably below that of the atmosphere, a refractory conductor (such as a bar of dense hard carbon) is maintained at a white heat by an electric current. Hair-like fibres or filaments gradually appear, attached to the conductor. These may be removed for use as the apparatus cools.—A. R. D.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Phenyl-piperidine. E. Lellmann. Ber. **20**, 680—681.

PHENYL-PIPERIDINE $C_5H_{10}NC_6H_5$ is produced in considerable quantity when piperidine (3 mols.) is heated at 250—270° with bromo- or iodo-benzene (1 mol.). It forms a strongly alkaline colourless oil of slight scatol-like odour. Its platino-chloride crystallises in long needles. The aromatic nitro-halogen derivatives react with piperidine more readily.—A. G. G.

Synthesis of Pyridine Bases. J. Plöchl. Ber. **20**, 722 and 723.

THE action of aldehydes upon a concentrated solution of ammonium chloride at a high temperature, appears to be a general reaction for the preparation of bases of the pyridine series. In this way paraldehyde gives collidine, and propionic aldehyde gives parvoline. The yields are rather small.—A. G. G.

Strychnine. C. Stoehr. Ber. **20**, 810—814; and 1108—1111.

BY the dry distillation of strychnine hydrochloride with lime (10 parts) there is formed in addition to ethylene and NH_3, picoline (β or γ?), a reduced pyridine base, skatole, and probably a collidine or lutidine. From this it appears that the strychnine molecule does not contain a quinoline residue (as assumed by Hanssen, *Ber.* 20, 460), but a pyridine and possibly also an indole residue.

The two oxygen atoms in strychnine are not present as hydroxyl, for they are not removed by heating with a large excess of PCl_5, the product of the reaction being *trichlorostrychnine.* This body forms very stable colourless crystalline salts, and is different from the trichlorostrychnine obtained by chlorination.—A. G. G.

Aesculetin and some Derivatives of Hydroxyquinol. W. Will and W. Pukall. Ber. **20**, 1119—1136.

AESCULETIN, found in the horse-chestnut, has been shown to be a di-hydroxy-derivative of cumarin, but endeavours made by various chemists to prepare it by the condensation of the ethereal salts of different acids with phloroglucinol have been unsuccessful; other experiments also showed that the only possible constitution of aesculetin was that of an ethereal derivative of hydroxyquinol. To settle this question, the authors have prepared these derivatives and compared them with aesculetin. After preparing the tri-ethoxyquinol $C_6H_3(OC_2H_5)_3$ [1 : 3 : 4], and a comparison of its properties, the author concludes that there can be no doubt that aesculetin is derived from the phenol corresponding to this substance, and future experiments must be made to show the position of the acrylic acid in the benzene ring.—G. H. M.

Ecgonine. E. Einhorn. Ber. **20**, 1221—1229. (Compare this Journal, 1886, 40, and 1887, 225.)

ECGONINE is a decomposition product of cocaïne. Merck has stated that when ecgonine hydrochloride is heated with phosphorus pentachloride and chloroform a new base is formed. The author, however, had previously to this prepared the substance in a much simpler manner, and since it appears to be formed from ecgonine by the simple abstraction of water, he proposes to call it *anhydroecgonine.* The following gives the preparation and properties of its chief compounds:—

Anhydro-ecgonine $C_9H_{13}NO_2$ is best prepared by boiling ecgonine hydrochloride with phosphorus oxychloride with an inverted condenser: the product is poured into water and a solution of iodine in hydriodic acid added. The periodide of anhydro-ecgonine is completely precipitated; this is washed with water and distilled in steam to rid it of free iodine; the colourless aqueous solution thus obtained is evaporated, and the iodide allowed to crystallise. It forms fine crystals of the composition $C_9H_{13}NO_2HI$. These are treated with moist silver oxide, the silver removed by sulphuretted hydrogen, and the free base crystallised from methyl alcohol. It forms colourless crystals melting at 235° with decomposition; it is easily soluble in water and alcohol, quite insoluble in ether, chloroform and benzene. It gives good crystalline salts with the haloid acids; the *hydrochloride* melts at 240—241°: the *platinum* double salt crystallises in yellow prisms, melting at 223°.

The *periodide* of anhydro-ecgonine $C_9H_{13}NO_2HI.I_2$, crystallises in violet plates, melting at 185—186°. The aqueous solution loses the excess of iodine on boiling. The *perbromide* forms orange crystals, melting at 154—155° with decomposition; the *bromide* melts at 122°. The substance admits of easy etherification. The *ethylanhydro-ecgonine* is an oil which forms crystallisable salts with haloid acids. The *hydrochloride*, $C_9H_{12}NO_2.C_2H_5.HCl$, forms white needles, melting at 243—244°. The *platinum* double salt $(C_9H_{12}NO_2.C_2H_5.HCl)_2,PtCl_4$, crystallises in yellow prisms, melting at 211°.

When anhydroecgonine hydrochloride is heated in a sealed tube with bromine, a substance crystallising in white crystals and melting at 183—184° is obtained. It appears to have the composition $C_8H_{12}NBr_2COOH.HCl$, and does not lose its bromine to a solvent; it also differs in behaviour from the perbromide of anhydro-ecgonine.

The author regards anhydro-ecgonine as *methylated tetrahydropyridylacrylic acid*: ecgonine as *methyl-tetrahydropyridyl-β-oxypropionic acid*: and cocaine as *methylic methyltetrahydropyridyl-β benzoyloxypropionate*, with the following formulæ:—Anhydro-ecgonine, $C_5H_4N(CH_3)H_3.CH:CH.COOH$.: ecgonine, $C_5H_4N(CH_3).H_3.CHOH.CH_2.COOH$: cocaine, $C_5H_4N(CH_3)H_3.CHO(OCC_6H_5).CH_2.COOCH_3$. Anhydro-ecgonine oxidised with potassium permanganate yields a crystalline substance.—G. H. M.

Eucalyptus and Eucalyptus Oils. Adrian. Nouv. Remed. 1887, 195.

THE eucalyptus oil of commerce is obtained from more than 150 species of eucalyptus, but *E. globulus* is the only one that yields the hydrocarbon eucalyptol discovered by Cloëz. In the south of France a yield of 0·4 to 0·7 per cent. is obtained by distilling the leaves of *E. globulus*, and 1kilo. of oil gives on the average 600grms. eucalyptol. The oil is fractionated, and the portion boiling between 170° and 175° separated. It is then treated with caustic potash and warmed, separated from the alkaline solution and fractionated repeatedly till a distillate having the constant boiling point 175° is obtained. A little below 170° 6 per cent. of a liquid with a pleasant smell, resembling that of valeraldehyde, passes over. The author considers Cloëz' formula for eucalyptol ($C_{24}H_{20}O_2$) unfounded, and regards it as a hydrocarbon consisting of a mixture of varying amounts of terebene and cymene.—C. A. K.

Lactic Acid Fermentation. M. Hayduck. Chem. Zeit. **11**, 151.

THE author has investigated the effect which lactic acid itself has upon the development of lactic acid bacteria. He finds that an addition of 0·1 per cent. of lactic acid distinctly retards the fermentation, whereas if 0·15 per cent. is added it stops completely. Now in practice about ten times as much lactic acid as this is produced. The apparent contradiction is explained by the fact that the liquids examined by the author only contained very small quantities of the lactic acid ferment: the presence of 0·15 per cent. of lactic acid does not check the fermenting power of the bacteria, but only prevents their rapid development. This explanation is supported by a set of microscopic observations made concurrently with determinations of acidity (no lactic acid having previously been added). It was found that at first the amount of acid produced was very small, because of the small quantity of ferment present; as the ferment developed the rate of production increased, until the very presence of the acid reacted prejudicially upon the development of the ferment, and so ultimately upon the further formation of the acid itself. The presence of 4 per cent. of alcohol hinders the lactic acid fermentation, and 6 per cent. stops it entirely. It acts even more prejudicially upon the butyric acid ferment: whereas acetic acid, on the other hand, is more readily formed in the presence of alcohol.—D. E. J.

On Ethyl Bromide. M. C. Traub. Chem. Zeit. **11**, 151.

As this is now used as an anæsthetic, it is important that it should be free from sulphur compounds, which have an injurious effect. Commercial ethyl bromide is prepared from phosphorus containing sulphur, which accounts for the presence of ethyl sulphide in it. For this reason the phosphorus method should not be employed; a much better preparation can be obtained by the method given in the French Pharmacopœia. A good preparation should be quite colourless, of a pleasant ethereal smell, and of sp. gr. 1·385—1·390. It should undergo no change when shaken up with pure sulphuric acid for three or four days; if the acid is coloured yellow, sulphur compounds are present. If it is shaken up with an equal volume of water, the water should neither colour litmus paper nor react upon silver nitrate.

—D. E. J.

Cali Nuts. Chem. Zeit. **11**, 633—634.

Calabar beans, by fraudulent intention, accident, or carelessness, are occasionally mixed with the seeds of other West African plants, such as those of the palm oil tree (*Elæis guineensis*) and of *Entada scandens*. The seeds of various species of *Mucuna*, more especially those of *M. cylindrosperma* (Cali nuts), often get into commerce as wild Calabar beans. Since they are said to possess similar properties to the true Calabar beans, and are somewhat similar in physical characters, botanists are divided in opinion as to whether Cali nuts are not a species of physostigma rather than of *Mucuna*. The seeds of *M. cylindrosperma* may be distinguished from the true Calabar beans by the former being cylindrical, of a reddish-brown colour, finely corrugated, and the hilum does not extend quite to the extremity of the bean at the end where the microphyle is visible, but forms there a slight projection. Both are used by the natives of West Africa as ordeal poisons.—W. E.

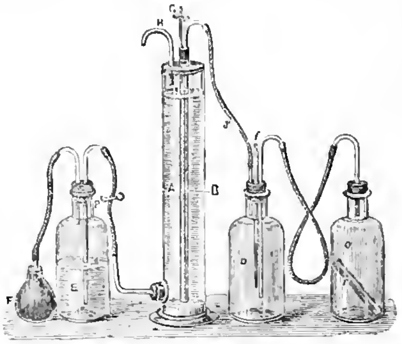
XXII.—ANALYTICAL CHEMISTRY.

Apparatus for Determining Carbonic Acid Volumetrically in Carbonates. D. Sidersky. Zeits. Anal. Chem. **26**, 336—338.

The apparatus, which is shown in Fig. 1, is of simple construction, and requires no stands or supports; the graduated tube B, which is used for measuring the carbonic acid, is placed in the glass cylinder A, and held in position by the cork above. The cylinder A is filled with water, and thus protects the gas from changes of temperature. The carbonate, or other substance to be analysed, is placed in the bottle C; the small india-rubber test-tube *r*, filled with HCl, is next introduced carefully, and the bottle closed by means of the stopper, in which is fixed the delivery-tube. The clips G and P are now opened, and the ball F is squeezed so as to force water from the reservoir E into A and B, until it reaches the zero of the graduation on the measuring-tube B. The clips are now closed, and the bottle C is tipped over so as to bring the acid in contact with the substance; by opening the clip P the water can be brought to the same level in A and B. The temperature of the evolved gas in D is noted, and the volume of the air in B read off at the same time.—D. E. J.



Some New Laboratory Appliances. E. Pollack. Rep. Anal. Chem. **7**, 287—288.

Fig. 1 represents a dropping funnel which allows of a constant outflow of the fluid. This is effected by a hollow stop-cock, to which a small tube is fused in such a manner that the interior of the stop-cock can communicate with the air when in a certain position. Another advantage of this arrangement is that it is possible to dry the air or to free it from CO_2 before allowing it to enter the funnel, by attaching to the side tube apparatus for absorbing this gas or the aqueous vapour. Fig. 2 is a flat funnel used instead of glazed paper in collecting precipitates previous to weighing them. Fig. 3 is a new reflux condenser with interior cooling action.—A. R.

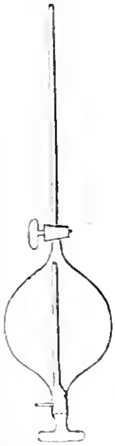


Fig. 1.

Fig. 3.

Simple Apparatus for Distilling Mercury in Vacuo. B. Nebel. Repert. Physik, 1887, **23**, 236.

An inverted bottle connected by a glass tube with a glass cylinder fitted into a movable wooden frame serves to supply the mercury to the distilling bulb, which is placed at the average barometric height above the cylinder, and which is connected to it by a tube fused into the bulb. The exit tube of the bulb is bent twice, and finally connected with a narrow vertical tube, the end of which is bent in a semi-circle and fused into a small trumpet-shaped vessel, from which a short side tube leads to the receiver. In order to start the distillation, the supply bottle is charged, and then the bulb exhausted by attaching a pump to a glass tube which fits inside the trumpet-shaped vessel connected with the receiver. The mercury is thus drawn into the distilling flask, where it is heated by a Bunsen burner. As soon as the distilled mercury fills the trumpet-shaped vessel to the height of the exit tube connected with the receiver the pumping is stopped, for now the mercury falling down the narrow tube connected with the distilling bulb acts like a Sprengel pump. The total vertical length of the tube is 850mm. The apparatus works continuously, and distils 500—600grms. of mercury per hour.—C. A. K.

Qualitative Method for the Detection of Sulphites in presence of Hyposulphates (Thiosulphates) and Sulphates. A. Villiers. Compt. Rend. **104**, 1177.

When an alkaline sulphite is precipitated with barium chloride the previous alkaline solution becomes neutral to test paper, while with alkaline bisulphites an acid solution results according to the equation :—

$$2KHSO_3 + BaCl_2 = BaSO_3 + 2KCl + H_2SO_3.$$

Thiosulphates behave like bisulphites, and can be detected in presence of sulphites by carefully neutralising the solution if previously alkaline with hydrochloric acid, and then treating with barium chloride. The acid solution is distilled, and the sulphurous acid tested for in the distillate.—C. A. K.

Solubility of Magnesium in Water containing CO_2. Kappel. Chem. Zeit. **11**, 137.

If a stream of carbonic acid is led for some time through distilled water in which magnesium wire is placed, the magnesium gradually dissolves, forming magnesium bicarbonate, and hydrogen is evolved. In the opinion of the author, this indicates the existence of the compound H_2CO_3.—D. E. J.

On a New Reagent for Copper Salts. Aliamet. Bull. Soc. Chim. **47**, 754.

This reagent produces in aqueous solution of copper salts a blood-red coloration like that of sulphocyanate of iron. The reagent itself is colourless, and is prepared by adding pyrogallic acid to neutral sodium sulphite. The reaction is very delicate; *e.g.*, a solution containing only $\frac{1}{3000000}$grm. of $CuSO_4$ per cc. gives a distinct orange-red coloration. Pyrogallic acid itself gives with copper salts a red colour; but the reaction is not nearly so delicate as when sodium sulphite is present.—D. E. J.

On the Determination of Ammonia in Soils by the Azotometric Method. Dr. Anton Baumann. Zeits. Anal. Chem. **26**, 302—312.

Of the three methods for estimating ammonia in soils—Boussingault's, Schlösing's, and the azotometric method—the first alone is capable of giving good results. It depends upon driving off the ammonia by means of magnesia at the boiling-point. Schlösing's plan of driving off the ammonia with caustic soda in the cold can only be applied to soils which contain little humus, for soda decomposes other nitrogenous constituents of humus soils, with evolution of ammonia. Knop-Wolf's azometric method, which is recommended in the text-books as being the best, is shown by the author to be quite unreliable, inasmuch as it is subject to three important sources of error. The method, as originally described, consisted in treating 200—300grms. of the soil with borax-solution and 50 cc. of bromine-water, shaking up well, and measuring in the azotometer the nitrogen evolved. The solution of borax was added with the object of preventing that contraction of the air in the evolution-flask which would otherwise occur on shaking up of soils with alkaline fluids. It is just this contraction which forms the first defect of Knop's method, for the author has shown that when humus soils are shaken up with alkalis in closed vessels, they absorb oxygen from the air; a contraction therefore occurs which diminishes the apparent amount of nitrogen evolved. When the soil under examination is very rich in humus, this contraction may even overpower the increase in volume due to the evolution of nitrogen, so that the reading of the azotometer becomes negative. Again, the addition of borax does not correct this error, for borax-solution is itself alkaline—as is shown by its behaviour towards indicators and ammonium salts—and it produces the same contraction as alkalis; it therefore increases the error, instead of diminishing it. Lastly, bromine-water not only sets free nitrogen from ammonia, but also from other nitrogenous substances, such as amido-compounds and albuminous substances. The error from this source is very serious, and may increase the apparent amount of ammonia by 400—4000 per cent. The author further criticises the modification of the method proposed by Knop (*Zeits.* 26, 1), and shows that it is subject to the same errors.—D. E. J.

Determination of Sodium and Potassium Chloride in Crude Potash. H. Focke. Rep. Anal. Chem. **7**, 285—286.

Most chemists have hitherto assumed, on the authority of Fresenius, that the chlorine contained in potash must be regarded as combined with potassium rather than with sodium. Dr. Ziurek, however, held that the chlorine is chiefly present as sodium chloride, and with a view to testing the accuracy of this idea, he undertook some experiments, which were not quite concluded before his death, and the author of this paper is publishing the results obtained by Ziurek. The method employed was as follows:—The residue obtained by evaporation of a crude potash solution, previously exactly neutralised with sulphuric acid, was extracted with alcohol of 85 per cent. strength. Determination of chlorine and potash were then made in this alcoholic extract, and the quantities obtained compared with those originally found in the crude potash. It appears that all the chlorine in the latter is found in the alcoholic extract. The following is the result of a few analyses :—

Chlorine in Potash, directly determined.	In Alcoholic Solution.		The latter corresponds to Chlorine.
	$Cl.$	$K_2O.$	
5·30%	5·23%	0·44%	0·33%
4·76	4·49	1·45	1·09
2·45	2·45	2·70	2·02
2·15	2·37	2·71	
2·62	2·54	1·50	1·13
1·68	1·68	1·94	1·49

—A. R.

Estimation of Sulphur by Weil's Method. C. Friedheim. Ber. **20**, 1483—1485.

The method proposed by Weil for the estimation of sulphur in sulphides decomposable by acids consists in absorbing the H_2S in ammoniacal $CuSO_4$, or Fehling's solution, and titrating the copper remaining in the filtrate with $SnCl_2$. The author has already shown (*Ber.* **20**, 59) that with employment of ammoniacal $CuSO_4$ the process gives incorrect results. He now publishes a series of analyses which show that the method is equally inexact if Fehling's solution is used; in this case the numbers are too high, probably from formation of oxysulphide.—A. G. G.

On a Reaction which can be employed for the Colorimetric Estimation of Phosphorus in Iron, Steel, etc. F. Osmond. Bull. Soc. Chim. **47**, 745.

When phospho-molybdic acid is dissolved in an acid solution of chloride of tin, a beautiful blue coloration is produced, the intensity of which is proportional to the amount of phospho-molybdic acid present. The author employs this reaction for the rapid determination of phosphorus in iron and steel. The solution of tin is prepared by dissolving 12grms. of the crystallised chloride in 80cc. of pure hydrochloric acid, and diluting with water to 1 litre. The precipitate of ammonium phospho-molybdate obtained in the usual way is filtered through asbestos (not through paper, because this absorbs the colouring matter), and after washing upon the filter is dissolved in a sufficient quantity of the tin solution; the filtrate is then made up, by means of the same solution, to a constant volume of 100cc. for every gramme of the metal used, and the depth of the coloration is determined. A series of solutions made up so as to contain known quantities of ammonia phospho-molybdate can be used for this purpose; these solutions keep well for several days. Crova's spectro-photometer can also be employed for estimating the intensity of the colour.—D. E. J.

Detection of Alcohol in Oil of Lemons. Dingl. Polyt. J. **264**, 520.

The oil to be tested is placed in a dry test tube, and a little powdered fuchsin is dusted over the inside of the test tube, above the oil, which is now heated to boiling. If it is free from alcohol, the fuchsin remains unchanged; but if the oil contains even 0·1 per cent. of alcohol, the solvent action of the latter produces a red edge round each particle of fuchsin.—D. E. J.

Determination by Titration of the Free Acid in Tannin Liquor. R. Koch. Dingl. Polyt. J. **265**, 33—41.

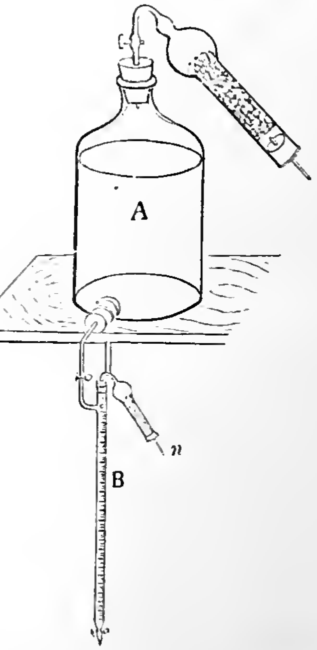
In a previous communication (*Ibid.* **264**, 395) the author recommended the use of albumen for the precipitation of tannin and the decolorisation of tannin liquor. He now finds the application of a gelatin solution more preferable. It is necessary, however, to adjust the concentration of the solution to the percentage of tannin in the liquor, otherwise difficulties in connection with the filtration of the precipitate may arise. A solution containing 2grms. of gelatin in a litre is applicable to most cases. The method is based on the fact that on treating tannin liquor with gelatin and nearly neutralising the mixture with standard alkali, a light-coloured filtrate is obtained which assumes a dark colour as soon as the point of alkalinity is reached. The mode of procedure is described in detail in the original paper, and the results of several test analyses are given. In conclusion, it is shown that powdered skin cannot be employed instead of gelatin, owing to the fact that it absorbs acid from tannin liquor.—D. B.

Estimation of Small Quantities of Paratoluidine in Orthotoluidine. C. Häussermann. Dingl. Polyt. J. **265**, 42—43.

Of the methods recommended for the estimation of para- and orthotoluidine (compare Lewy and Lunge, this Journal, 1883, 242; and 1885, 339), the process based on the titration of the para compound with oxalic acid in an ethereal solution (Rosenstiehl, *Ibid.* **204**, 326) has been mostly adopted. It is not, however, wholly free from error, owing to the fact that the amount of ether to be used is frequently insufficient to completely dissolve the "ortho-oxalate" produced by the reaction. The author suggests the following method:—A solution containing 88grms. of crystallised oxalic acid in 750cc. of water and 43cc. of hydrochloric acid of 22° Bé. is heated in a porcelain basin to from 70—75° and treated with 10grms. of the toluidine under examination. When the precipitate which separates has been entirely redissolved, the mixture is allowed to cool gradually to 30—35° until the oxalate shows signs of crystallisation on the surface of the solution. It is then filtered through cotton, and the residue washed with a few drops of water. The precipitate forms small colourless scales having a dull appearance. The filtrate on standing deposits a further portion of crystals which are collected on a separate filter and washed. This operation is repeated until crystals are obtained having a lustrous appearance. These consist of the pure "ortho-oxalate," and are readily distinguished from the crystals of the para compound. The crystalline fractions are then treated with a solution of sodium carbonate and subjected separately to distillation. The solidifying point of the distilled bases is determined by cooling a fraction of each distillate with ice. If the oil solidifies by merely agitating it, the crystals are collected on a tared filter, and after drying over caustic soda, weighed as paratoluidine. If, however, the addition of a few crystals of pure paratoluidine is required to induce solidification, only one-half of the mass is calculated as paratoluidine. If, on the other hand, it is impossible to solidify the base obtained from the distillation of the first crystalline fraction, orthotoluidine only is present in the sample under examination. With good toluidines, it generally suffices to collect and distil two fractions, in which case the base from the second crystallisation mostly constitutes a perfectly liquid oil. This method being inapplicable to mixtures containing more than 10 per cent. of paratoluidine, it is suggested to dilute such mixtures by the addition of pure orthotoluidine.—D. B.

New Method for the Quantitative Determination of Starch. A. V. Asbóth. Rep. Anal. Chem. **7**, 299—302.

The author maintains that unsatisfactory results are obtained in determinations of starch, when the method employed is based upon the inversion of sugar, formed as an intermediate product, since maltose, dextrose, and levulose are partly decomposed by boiling with dilute acids. He proposes to replace the methods hitherto employed by one which depends upon the formation of a barium salt of starch, to which he assigns the formula $BaO.C_{24}H_{40}O_{20}$. This salt is sparingly soluble in water and insoluble in dilute alcohol. In making a determination a weighed quantity of starch is saccharified with water, then mixed with an excess of normal baryta solution, dilute alcohol added to make up to a certain volume and, after the precipitate has settled the excess of baryta is titrated back with acid.



The author also describes the apparatus he employs for storing and titrating with baryta solution. The latter is contained in the bottle A, and the drying tube attached to the neck of the same is filled with quicklime. The burette B, which is in direct connection with the bottle, may be filled with the solution by opening the stop-cock, and the small drying tube *n* is filled with dry KOH, thus preventing the entrance of any CO_2. Numbers are appended which seem to testify to the excellence of the method employed. The author finally gives a detailed account of the entire analysis of various cereals.—A. R.

The "Helfenberger" Method of Estimating Morphia.

Eugen Dieterich. Chem. Zeit. **11**, 144.

Further study of the best conditions for carrying out this analysis has led the author to the following improved methods:—

I. *Opium.*—Rub up 6grms. of finely-powdered opium with 6grms. of water, transfer to a weighed flask, and make up with water to 54grms.. Allow the maceration to proceed (with frequent stirring) for one hour, and filter through a quick filter of 10cm. diameter. To 42grms. of the filtrate add 2cc. of normal ammonia, mix well, and filter as before. Place 36grms. of the filtrate (=4grms. of opium) in a tared Erlenmeyer's flask, add 10grms. of ether and 4cc. of normal ammonia, shake gently until the liquid becomes clear, then cork up the flask and leave it. After standing for 5 hours, transfer the ethereal layer as completely as possible on to an ordinary filter of 8cm. diameter, add another 10grms. of ether to the solution in the flask, shake gently, and again transfer this to the filter. After this has run through, pour the aqueous solution on the filter: the morphine crystals will now be found attached to the walls of the flask. Wash the flask twice with 5cc. of water saturated with ether, dry the flask and filter at 100°, transfer the small quantity of morphia on the filter to the flask, and again dry until the weight becomes constant.

II. *Opium-extracts.*—Dissolve 3grms. of the extract in 40grms. of water, mix with 2cc. of normal ammonia, and filter at once through a quick filter of 10cm. diameter. 30grms. of the filtrate (=2grms. of the opium-extract) are then treated as above.

The method depends on the peculiar behaviour of the salts of morphia, which, when decomposed by ammonia, remain clear at first, and only deposit the morphia (in crystals) slowly.—D. E. J.

Estimation of Emetine in Ipecacuanha and its Extracts.

M. Lignon. Chem. Zeit. **11**, 148.

Analysis of the Root.—Grind up 25grms. of the root in a mortar with 25cc. of water, mix with 20grms. of slaked lime, and after this has been well rubbed up, add 30grms. more of slaked lime. Extract for 3 hours in a suitable extraction-apparatus with 300cc. of ether, filter the ethereal solution (about 200cc.) if it contains any solid matter, and make it up to 200 or 250cc. Place 50cc. of the solution in a 100cc. flask; to this add 10cc. of seminormal sulphuric acid and 4 to 5 drops of freshly-prepared concentrated extract of campeachy wood. After thorough shaking the mixture divides into a colourless ethereal layer and a yellow aqueous layer. The acids contained in the solution are neutralised by adding seminormal ammonia drop by drop until the aqueous layer is coloured red.

Analysis of the Extract.—Mix 5grms. of the extract with 5grms. of water, and add gradually 25grms. of slaked lime, rubbing it up thoroughly with the mixture. A powdery mass is thus obtained which can easily be extracted: it is to be treated with 200cc. of ether as above. According to the experiments of the author, good ipecacuanha ought to contain about 1·45 per cent. of emetine, or 1·663 per cent. of the hydrochloride.

—D. E. J.

A New Method of Estimating Glycerol.

R. Diez. Chem. Zeit. **11**, 148.

0·1grm. of glycerol is dissolved in from 10 to 20cc. of water, and shaken up in a flask with 5cc. of benzoyl chloride and 35cc. of 10 per cent. caustic soda solution. During the reaction the flask should be cooled, and after the benzoyl compound has separated out it is collected upon a dried filter, washed with water, and dried on the filter at 100° for 2 or 3 hours. 0·1grm. of glycerol corresponds to 0·385grm. of the ether. If it is proposed to estimate the amount present in wines or beer, the glycerol should first be isolated in the usual way, and then examined as above and under the conditions there described (*i.e.*, not more than 0·2grm., and in a 0·5 per cent. to 1 per cent. solution). All carbohydrates should be carefully removed, because they also yield, when treated with benzoyl chloride and soda, ethereal salts which are insoluble in water and alkalis. The following directions are to be observed in the several cases described: *A. Fermented wines poor in sugar.*—Take 20cc. of the wine, and after driving off the alcohol, evaporate it nearly to dryness with an excess of lime: extract the residue while still warm with 20cc. of 96 per cent. alcohol. After cooling add 30cc. of dry ether, filter, and wash with a mixture of alcohol and ether (2 : 3). After evaporating off the solvent, dissolve the glycerol in water, and proceed as above. *B. Sweet wines.*—A larger amount of lime should be used, and 1grm. of sand added to it. Twice the quantity of alcohol and ether should be taken. *C. Beer.*—Evaporate 50cc. with lime and sand nearly to dryness. Allow the residue to cool, grind it to a fine powder, and treat it with 50cc. of 96 per cent. alcohol; then add 75cc. of dry ether and allow it to stand. The glycerol obtained from the filtered solution is dissolved in from 5 to 10cc. of water and treated as above with soda and 2 to 3cc. of benzoyl chloride.—D. E. J.

Adulteration of Rape Oil with Mineral Oil.

H. Focke. Rep. Anal. Chem. **7**, 286—287.

Rape oil is occasionally found to be mixed with mineral oil. A specimen examined by the author contained 20 per cent. of oil which could not be saponified. The specific gravity of the admixture was the same as normal rape oil, viz., 0·9144, and its reactions appear to show that it is a mixture of a mineral and resinous oil. For lubricating purposes this adulteration causes a serious deterioration in the value of the rape oil, and in some countries where rape oil is also used for cooking purposes, several cases of poisoning occurred which were traced to the presence of mineral oil in the rape oil employed.—A. R.

New Books.

Coal-tar and Ammonia. The Second and Enlarged Edition of "A Treatise on the Distillation of Coal-tar and Ammoniacal Liquor." By George Lunge, Ph.D., Professor of Technical Chemistry in the Federal Polytechnic School, Zurich. London: Gurney & Jackson, 1, Paternoster Row. 1887.

In its second edition this important, and indeed unique work, has grown to double the size of the first edition. It now takes the form of a somewhat thick 8vo volume, bound in cloth, and containing Preface, Table of Contents, and 727 pages of subject matter, including an introductory chapter, and at the end of the book a chapter of Addenda and an Appendix. An Alphabetical Index concludes the work. With the text are interspersed 191 excellent woodcuts. The plan of the work may be roughly sketched as follows:—Chap. I. Introductory. Chap. II. Processes for Obtaining Coal-tar; (A) the Production of Coal-tar at the Gas-works; (B) Tar and Ammonia obtained as By-products in Coke Making; (C) Tar and Ammonia from Gas Producers; (D) Tar and Ammonia from Blast-furnace Gases; (E) Preparation of Mixtures similar to Coal-tar, by the Decomposition of certain vapours at a high temperature. Chap. III. The Properties of Coal-tar and its Constituents. Chap. IV. The Applications of Coal-tar without Distillation. Chap. V. The First Distillation of Coal-tar. Chap. VI. Pitch. Chap. VII. Anthracene Oil. Chap. VIII. Creosote Oil. Chap. IX. Carbolic Acid and Naphthalene. Chap. X. Light Oil and Crude Naphtha. Chap. XI. Rectification by Steam. Final Products. Chap. XII. Sources from which Ammonia is obtained. Chap. XIII. The Composition and Analysis of Ammoniacal Liquor and Properties of its Constituents. Chap. XIV. The Working up of Ammoniacal Liquor.

Die Chemische Technologie der Brennstoffe. Von Dr. Ferdinand Fischer. (Bolley's Handbuch der Chemischen Technologie). 45, Bd.I. 3.2. *Zweite Lieferung.* Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn. 1887. London: H. Grevel & Co., 33, King Street, Covent Garden, London.

The second part of this important work has now made its appearance, and takes the form of an 8vo volume, bound in paper cover. The first part was issued in 1880. The price of this second part is 8s. The work as a whole is illustrated with 281 woodcuts, the text covering 105 pages. A concise Table of Contents, in lieu of alphabetical index, is given at the end. The work opens with some chapters on the MEASUREMENT OF HEAT, followed by others on the MEASUREMENT OF LIGHT. The subject of the INVESTIGATION OF FUEL is next taken up, various solid and gaseous fuels being treated of, and also all the principal varieties of calorimeters. The INVESTIGATION OF ATMOSPHERIC AIR then follows, and is very fully dealt with. The subject of the EXAMINATION OF FIRE-GASES is then considered in detail, and the methods of Bunsen, Winkler, Bunte, Liebig, Regnault, Frankland, and Kempel, etc., for measuring and otherwise testing gases, are given. The INVESTIGATION OF ILLUMINATING GAS forms the closing subject of the treatise, and it is very completely treated.

MELTING AND BOILING POINT TABLES. PHYSICO-CHEMICAL CONSTANTS. BY THOMAS CARNELLEY, D.Sc., F.C.S., F.I.C., Professor of Chemistry in University College, Dundee. Vol. II. London: Harrison & Sons, 69, Pall Mall. 1887.

PROF. CARNELLEY, with this second volume, completes a really great work, the preparation of which, as he states in the Preface, has been extending over 10 years. Vol. II. contains more than 32,000 melting and boiling point data, which, with those given in the first volume, make a total of over 51,000. The book presents the form of a quarto volume, strongly bound in cloth, with short Preface, Table of Contents, and matter covering 709 pages, dealing with Organic Compounds of from 4 to 708 elements, also special elements. This brings the reader to Part III., which is devoted to:—1. Vapour tension and boiling point tables of simple substances. 2. Ditto of mixed substances, such as mixed liquids and saline solutions. 3. Freezing and melting points of mixtures, including cryohydrates. 4. Miscellaneous melting and boiling point data, such as melting and boiling points of fats, oils, etc. 5. Volumes and corresponding years of issue of the more important chemical and physical periodicals. 6. Alphabetical index of root carbon compounds. The work is of such a kind that any compound can be speedily looked up, and being once found, a glance serves to inform the reader as to its constitution, formula, boiling and melting point, authority, original works of reference, and references to "Watts' Dictionary" and the *Journal of the Chemical Society.* In point of fact, it is a kind of condensed Dictionary of Chemistry that would, uncondensed, occupy eight or nine volumes, and cost four times the amount of this work. Being exceedingly handy for immediate reference, it combines economy in every form. The price of the work is for each of the two vols. £2 2s., net cash £1 12s. each.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

FRANCE.

Classification of Bromides and Iodides of Ammonia.

A circular, dated 20th July last, has been issued by the French *Direction General des Douanes,* from which it appears that the Committee of Arts and Manufactures has given the opinion that bromides and iodides of ammonia should be assimilated in the tariff to salts having potassium for their base, and, consequently, pay duties of 100 and 350 francs per 100 kilogrammes, respectively; also, that this decision has been ratified by the Departments of Finance and Commerce.

SPAIN.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Kilogramme = 2·2011b. avoirdupois. Peseta = 9$\frac{5}{8}$d.)

The following decision has recently been given by the Spanish Customs authorities:—

Ground colours for painting, composed of two elements, organic and inorganic, and easily soluble in alcohol and ether. —Category 72. Duty 75 cents. per kilog.

SWITZERLAND.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Franc = 9$\frac{5}{8}$d.)

The following decisions affecting the classification of articles in the Swiss Customs Tariff have been given by the Swiss Customs authorities during the month of July last:—

Pepsine wine.—Categories 11 and 12. Duties from 30 to 100 francs per quintal.

Hartshorn oil, raw.—Category 16. Duty, 30 francs per quintal. (Formerly included in Category 17.)

Camphor oil.—Category 18. Duty, 2 francs per quintal.

Chrome ochre.—Category 36. Duty, 3 francs 50 centimes per quintal.

NEW CUSTOMS TARIFF OF BRAZIL.

(Continued from page 16[illegible] of the last Number of the Board of Trade Journal.)

(*Note.*—Kilogramme = 2·2011b. avoirdupois. Litre = 0·22 Imp. gallon. Milreis = 2s. 3d.—nominal value.)

Note.—The translation of the Brazilian Customs Tariff will be continued in the next number of the *Journal*.

New Customs Tariff of Portugal.

With reference to the notification which appeared on page 390 of the May number of the *Board of Trade Journal*, a despatch, dated the 18th August last, has been received from Mr. M. de Bunsen, Her Majesty's Chargé d'Affaires at Lisbon, enclosing translation of the new Portuguese Customs Tariff, which will come into operation on the 1st of October next.

Tariff Proper.

(Note.—The column headed "Total Duty" refers to the duties leviable under the Portuguese General Tariff as modified by treaties between Portugal and other Powers. The additional duties for Custom House fees and Harbour Works, in the case of articles not governed by any of the treaties, are stated to be included in the rates specified in the final column.)

(*Note.*—Kilogramme = 2·204lb. avoirdupois. Decalitre = 2·2 Imp. Gallons. Milreis = 4s. 6d.)

57	Shreds and rubbish for paper paste, and paste in any shape for paper manufacture.
58	Ice.
59	Manures for agriculture.

ITALY.

Classification of Articles in Customs Tariff.

(*Note.*—Quintal = 220·4lb. avoirdupois. Kilogramme = 2·201lb. avoirdupois. Lira = $9\frac{6}{10}$d.)

The following decisions affecting the classification of articles in the Italian Customs Tariff have recently been given by the Italian Customs authorities:—

Phenic acid, containing 60 per cent. of light oil.—Category I., No. 8*a*. Duty, 38 lire per quintal.

Chlorhydrate of quinine.—Category III., No. 32*b*. Duty, 5 lire per kilog.

Carbonate of magnesia, natural.—Category III., No. 15. Duty, 5 lire per quintal.

NEW SOUTH WALES.

Modification of Customs Duties.

With reference to the notification that appeared on page 267 of the December number of the *Board of Trade Journal*, a communication, dated the 20th July last, has been received from the New South Wales Government statistician, enclosing copy of an Act modifying the Customs duties on certain articles imported into that colony. The following statement shows the new duties imposed by this Act which, up to the 30th of September next, is to be read with the previous Act of 1886, notice of which appeared in the December number of the *Journal*—that is, the old duties are leviable except in regard to the articles specified in the following Schedule (on which the new duties came into force on the 30th March last, and were to remain in force until the 30th September next, after which date the new tariff alone comes into operation):—

Classification of Articles.	Rates of Duty.
Cement ....per barrel	£0 2 0
Essences, flavouring and fruit, containing not more than 25% of proof spirit ....per gallon	0 4 0
Containing more than 25% of proof spirit, per gallon	0 11 0
Glucose, liquid and syrup ....per cwt.	0 3 4
„ solid .... „	0 5 0
Naphtha or gasoline ....per gallon	0 0 6

ITALIAN TRADE DURING THE FIRST SIX MONTHS OF 1887.

Ib., page 282.

ASSOCIATIONS FOR THE DEVELOPMENT OF THE EXPORT TRADE IN GERMANY.

A despatch, dated the 23rd August last, has been received from Mr. R. Milbanke, her Majesty's Secretary of Legation at Coburg, respecting the forming of an association at Gotha for the development of the export trade. The following is an extract from the despatch in question:—

"It is intended, according to the local press, to found at Gotha an association for the development of the export trade of the manufactures of this part of Germany. Similar associations *(export-vereine)* have been established in various parts of the Empire with the object of facilitating the export of German goods to foreign countries by enabling the individual manufacturers to obtain, with little trouble, and but small cost, information as to the best markets for their goods, the kind of articles which will find most ready sale, etc.

"These associations intend, moreover, it is stated, to appoint representatives in the great commercial centres, as well as travelling agents, whose business it will be to furnish reliable information respecting the goods to be exported, and the state of the market as affecting the manufactures of the district to which they belong.

"It appears now to be considered advisable, in the interests of Thuringian trade, to establish such an association at Gotha."

EGYPT.

Drug Trade of Alexandria.

The exports of drugs from Alexandria during the last two years were as under. The effects of the Soudan war are traceable in the enormous reduction in the quantity of gum arabic exported:—

	1886.	1885.
Drugs proper	£37,131	£29,287
Chemicals, medicines, and perfumery	11,699	9,513
Gum Arabic....................	11,717	100,112
Wax	9,879	11,867

while among the imports the following are enumerated:—

	1886.	1885.
Indigo	£181,665	£251,822
Other dyes	36,791	43,698
Soap	131,608	112,618
Chemicals and perfumery	112,335	107,785
Olive oil	80,110	93,031
Spices	49,828	67,111

FRENCH COLONIES.

Vanilla-growing in Réunion.

The quantity of vanilla exported from the island of Réunion in 1885 was 111,229lb. (value £51,831), while in 1886, 110,308lb. (value £53,752) were shipped. The high prices lately realised by vanilla on the European markets have been a great temptation to many persons in Réunion to convert what little land they possess into vanilla plantations; but this happy state of things is not destined to a long life, vanilla being an article for which the demand is restricted, and its over-production must necessarily be attended by a great fall in value.

Essential Oils.

The industry of perfume manufacture is assuming considerable proportions in Reunion. At present the industry is mainly confined to the manufacture of essence of geranium, great tracts of land having been devoted to the cultivation of this plant. Other perfumes are as yet made on an insignificant scale only; but this industry may assume large proportions.

JAPAN.

Nagasaki Drug Trade.

The value of the imports into Nagasaki of Western (European ?) drugs, medicines, and chemicals in 1886 was £5037, against £3551 in 1885. Of dyes and paints £3982 worth was received in 1886, and £1876 the year before.

The exports include:—

	1886.		1885.	
	lb.	£	lb.	£
Camphor	5,096,674	76,194	4,288,918	80,300
Cuttlefish..........	2,017,472	39,822	2,166,091	38,444
Drugs (sundry)	—	2,200	—	3,290
Sulphur	1,061,356	1,716	1,053,604	2,241
Vegetable wax....	151,641	2,615	385,538	6,850

Sulphur Exports.

In 1886 4117 tons of sulphur were exported from Hakodate, of a value of £7960 6s. 8d., against 6260 tons 15cwt., valued at £11,529 7s. 6d., in 1885, being a decrease of 2190 tons and £6569 0s. 10d. The production was about the same as in 1885, and the prices did not vary. Of the quantity shipped, about 950 tons went to San Francisco and the remainder to New York. At the end of the year there were some 2500 tons of sulphur on hand, owing to difficulty in obtaining suitable vessels to take it away. It is anticipated that the production of sulphur during 1887 will be greatly in excess of former years, as a company has been formed to work the sulphur mines at Atosanobori, near Kushiro, and a line of rails will be laid from the works to Shibecha, a distance of nearly twenty-five miles; thence the sulphur will be conveyed by river to Kushiro, a distance of about forty-four miles. Hitherto great difficulty has been experienced in conveying the refined sulphur from the works to the river.

PERSIA.

Bushire Exports.

The following articles figure among the exports of the port of Bushire :—

	1886.	1885.
	Value	Value
Drugs and medicines	£2,216	£4,010
Dyeing and colouring materials	4,387	4,126
Gum	4,978	5,328
Opium	303,071	340,240
Perfumery	9,025	6,974

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

(1.) *Imports into the United Kingdom from Spain.*

Principal Articles.		July, 1886.	July, 1887.

ANNUAL PRODUCTION OF ALKALI, ETC., IN UNITED KINGDOM.

By the kind assistance of Mr. E. K. Muspratt, hon. sec. to the Alkali Manufacturers' Association, I am enabled to append a tabular statement of the amount of the various products of the soda industry, annually produced from the year 1877 to 1886.

Year.	Salt decomposed.	Alkali 48 %.		Soda Crystals.	Caustic Soda.	Bleaching Powder*	Bi-carbonate of Soda.	Total.
		Lebl'nc Process	Ammonia pr'cess					
1877	578,201	217,556	6,220	169,769	74,663	105,529	12,109	1,164,017
1878	568,542	196,876	11,116	170,872	81,612	105,044	11,756	1,118,818
1879	615,287	230,683	15,526	185,319	86,511	115,290	13,083	1,126,699
1880	700,016	266,093	18,800	192,926	106,384	131,606	13,539	1,429,361
1881	675,099	238,687	20,400	203,773	108,310	135,826	12,853	1,394,948
1882	679,935	233,213	39,000	180,816	116,861	135,170	14,115	1,399,143
1883	705,732	227,281	52,750	188,678	119,929	141,868	12,609	1,452,188
1881	690,502	204,072	61,480	182,567	111,639	128,651	11,576	1,423,487
1885	722,472	181,597	77,530	202,705	111,954	132,761	15,179	1,180,198
1886	713,112	165,782	85,000	182,379	153,884	136,234	15,083	1,454,465

* This includes chlorate of potash, taking 5 tons of bleaching powder for 1 ton of chlorate. The amount of chlorate now made is 7000 tons per annum.

STATISTICS OF THE GERMAN SODA INDUSTRY.

(From a lecture delivered before the British Association at Manchester, by Mr. A. E. Fletcher, H.M. Chief Inspector under Alkali, etc. Works Regulation Act.)

By the kindness of Mr. Hasenclever, of Aachen, I am enabled to give the following statistics of the German soda industry. There has been a great development of it since the year 1879, when a change was made in the excise regulations which affect the trade. At that time, and for some years previously, soda, equal to about 27,000 pure carbonate, had been imported from abroad, this being about 40 per cent. of the quantity consumed in the country. Since that period the production has increased so as to stop importation, and to leave a small balance for export. At the same time the price has fallen from 20s. to 8s. per kilo—48 per cent. soda ash.

There are in Germany twenty-four alkali works, from which the yearly output is a quantity equivalent to 150,000 tons pure carbonate. This is against an output in 1878 of 42,000 tons. This rapid growth is shown in the following tabular statement:—

Import and Export of Foreign Soda to or from Germany. Amount given in tons.

Year.	Soda Ash.	Caustic.	Crystals.	Bi-carbonate.	Total Calculated as Pure Carbonate
1872	7,513	1,331	10,977	238	12,211
1873	10,101	1,858	12,306	472	16,093
1871	15,413	3,751	11,040	401	22,638
1875	16,064	5,980	11,381	517	26,101
1876	14,412	7,831	13,253	503	27,500
1877	14,530	7,915	10,679	510	26,787
1878	14,111	9,275	9,219	452	27,474
1879	15,911	6,887	10,686	366	26,475
1880	6,061	9,373	10,053	263	20,512
1881	6,310	5,266	10,833	327	16,132
1882	5,598	6,131	7,332	297	15,251
1883	887	4,748	2,076	206	7,917
1884	*7,318*	1,973	2,037	250	*3,305*
1885	*8,962*	2,299	282	112	*6,270*
1886	*9,150*	676	*1,759*	120	*10,204*

* The figures printed in italics indicate exports, the plain figures imports.

Mr. Hasenclever adds that it is, in his opinion, impossible for Germany to carry on permanently an export trade in soda products, since in England all the raw materials for that industry are cheaper, and the alkali works are better situated in relation to the seaports.

MISCELLANEOUS.

CHILIAN BORAX.

From some analyses made by Senor Emil Eisele, of Valparaiso, and by Mr. J. Clark, of London, of several samples of crude Chilian borax, it would appear that Chili is capable of producing at least as good borax as California, the quality being equal to a good deal of that which comes from Italy. The attempts which are being made to open up a borax industry in Chili would, therefore, seem likely to prove successful.

TRADE IN NEW PERFUMES.

The Danish *Archiv for Pharmaci of teknisk Chemi* for July of this year describes two new vegetable perfumes which have lately become articles of commerce. One of these is a kind of *xylopia* from the province of Chirigui in Costa Rica. The odour closely resembles that of *canaga odorata*, and the flowers are now used, like those of that plant, in the manufacture of ylang-ylang. The other is named *ouco*, and is the extremely odorous blossom of a kind of acacia-tree which is found in Central Africa, and which Serpa Pinto was the first to describe. The *ouco* flowers are brought down the Cubangin river for sale; they cover the trees on which they grow with such profusion that they fill the atmosphere with the overpowering richness of their scent.

PRODUCTION OF MALVA FIBRE IN BRAZIL.

The Belgian *Bulletin du Musée Commercial* for the 13th August last, quotes from the *Journal Commercial et Maritime* an article on the growth of *malva* in the province of Céara in Brazil. Until lately this plant, the *orena lubata*, was looked upon as a weed; it now proves to be a considerable source of wealth. The fibre of the *malva* forms an excellent material for the manufacture of sacks, and is found to take the place of jute. It is beginning to be largely exported for manufacturing purposes to Europe. The preparation of the *malva* fibre is easy and cheap, and if machinery of a suitable kind were introduced from Europe it might be produced on a large scale. The journals of Céara assert that their province contains in abundance other textile plants, which need only to be prepared to become a source of revenue.

Imports of Medicines.

The following table shows the amount of duty collected by the Customs on the importation of the articles named for the years ending March 31, 1886 and 1887, respectively :—

——	1887.	1886.
	£.	£.
Chloroform	2	6
Chloral hydrate	979	1015
Collodion	16	6
Ether, sulphuric	15	5
Ethyl. iodide of	—	—
Naphtha, purified	—	—
Soap, transparent, in the manufacture of which spirit has been used	180	224
Varnish containing alcohol	112	91

As the duty on chloroform is 3s. per lb., it appears that the total quantity of that article imported from abroad last year was under 14lb. The duty on chloral hydrate is 1s. 3d. per lb. The total import of the chemical for home consumption was therefore 15,664lb.—*C. and D.* 10. 9. 87.

Recent Trade Blue Books.

Mining and Mineral Statistics of the United Kingdom of Great Britain and Ireland, including Lists of Mines and Mineral Works for the year 1886, and a list of plans of abandoned mines. (C—5132) Price 3s. 7d.

Special Report from the Select Committee on Merchandise Marks Act (1862) Amendment Bill, together with the Proceedings of the Committee Minutes of Evidence and Appendix. 203. Price 4s. 4d.

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

APPLICATIONS.

11412 B. H. Thwaite, Liverpool. Improvements in methods of calcining and heating argillaceous, calcareous, and metalliferous substances and any mixture thereof, and in apparatus therefor. August 22

11456 W. S. Squire, London. Improvements in machinery for the separation of solid matters from liquids, and for washing out and exhausting the solid matters so separated. August 23.

11473 C. Kasefang, London. Taps or cocks specially adapted for the delivery of fluids under pressure. August 23

11519 P. Hodkinson, London. Apparatus for consuming smoke in steam-boiler and other furnaces. August 24

11549 G. Large, Wolverhampton. A water tuyere with a false nose or nozzle for use in hearths, cupolas, furnaces, etc. August 25.

11609 J. E. Warren, London. Means and apparatus for filtering water and other fluids. Complete specification. August 26

11622 N. Petersen, London. Improvements in furnaces. August 26

11628 C. Howe, B. Beckwith, and J. H. Beckwith, London. Apparatus for generating secondary steam ; specially applicable for distilling water. August 27

11636 R. Robson, Leeds. Atmospheric injector, for improving draught and consuming smoke in furnaces. August 27

11780 R. Cahn, London. Cooling apparatus. , August 30

11811 J. H. Hayes, London. Improved means for regulating the supply of gas and other fluids or liquids. August 31

11865 R. Gough, London. New or improved filter. September 1

11876 F. W. Cannon, G. P. Addison, and F. R. Burnett, London. Method and apparatus for generating steam. September 1

11877 J. Nicholas and H. H. Fanshaw, London. Construction of water or liquid gauges. September 1

11887 W. Fairweather—From the Babcock and Wilcox Company, United States. Drumheads and manifolds for sectional steam generators. Complete specification. September 2

11894 B. D. Healey, Bamber Bridge. Making and working furnace rocking bars. September 2

11929 B. Willcox—From M. Perret, France. Firebars or grates for furnaces. September 2

11981 W. Leigh, London. Amalgamating apparatus. September 3

11984 H. F. Green, London. Processes and apparatus for producing currents of air, spray, and gas, and for purifying, disinfecting, and chemically treating the same. September 3

12003 J. R. Alsing, London. Method of and apparatus for reducing sawdust, straw, and other vegetable substances to an impalpable powder or to a pulp, the apparatus being also applicable for pulverising hard substances. Complete specification. September 5

12038 J. S. Doran—From J. Reilly, United States. Heating apparatus. September 6

12071 J. von Ehrenwerth, London. Improved regenerative gas furnace with periodical action. Complete specification. September 6

12088 R. H. Brownhill, Manchester. Rotary pumps for raising and forcing liquids. Complete specification. September 7

12153 F. H. Danchell, London. Filter-presses. September 8

12169 P. Altieri, Naples. Preventing and removing the incrustations in steam boilers—known as "Vegetable Disincrustant." Complete specification. September 8

12180 G. Seagrave, London. Apparatus for heating or cooling air, gas, or other fluids. September 8

12216 H. L. Currier, London. Method and apparatus for removing the scale and other deposits from steam boiler and other tubes. Complete specification. September 9

12249 W. McElroy and H. Connett, London. Machines and apparatus for carbonating liquids. September 9

12293 W. P. Thompson—From W. Jäger (W. Pataky), Prussia. Centrifugal machine filters. Complete specification. September 10

12352 T. L. G. Bell, London. Means and apparatus for distilling sulphur, tar, rosin, arsenic, sal-ammoniac, and the like. September 12

12357 R. M. Bryant, London. Anti-incrustation preparation for steam boilers. September 12

12455 H. W. Lewis, London. An improved press for compressing cotton, jute, sewage, clay, china clay, small coal, artificial fuel, tar, yeast or barm, etc., into partly solid blocks. September 14

12594 J. H. Hayes, London. Means for regulating the supply of gas and other fluids or liquids. September 16

12627 G. F. Deacon, Liverpool. Apparatus for disintegrating the flow of liquids. September 17

12631 O. Imray—From La Compagnie Industrielle des Procédes Raoul Pictet, France. An improvement in refrigerating apparatus. September 17

12685 D. Mellor, London. Furnaces and furnace bars. September 19

*COMPLETE SPECIFICATIONS ACCEPTED.**

1886.

12475 J. Y. Johnson—From L. Labeyrie. Automatic valve for steam and other pipes or conduits conveying fluids under pressure. August 31

12907 A. Brin and L. Q. Brin. Apparatus for combustion of liquid, gaseous, or pulverulent fuel, for generating steam, etc. September 14

13605 J. Cooke. Composition for preventing and removing incrustation and corrosion in boilers. September 3

13789 F. Siemens. A combined evaporating and calcining furnace. August 27

13861 J. Bernhardi. Apparatus for distilling, condensing, heating, cooling, and extracting operations. August 31

13959 J. Howie and T. Groves. Open kilns. September 3

14141 R. Cunliffe and J. Lund. Apparatus for calcining, drying or roasting materials, and extracting gases or acid therefrom. September 10

14349 G. Dietrich. Apparatus for promoting consumption of smoke by means of air and steam jets. September 14

14415 E. A. Cowper. Filter-presses. September 21

14535 C. A. Sahlströhm. Apparatus for burning oil, tar, and similar substances. September 17

14643 T. Gilmour. Feed-heating apparatus. September 17

14873 H. H. Lake—From M. Hanford and C. C. Hanford. See Class XVI.

14967 E. O. Cooper and W. T. Cooper. Preventing and removing calcareous incrustations. September 21

15006 T. Routledge—From A. Abadie, France. Apparatus for crushing, grinding, triturating, disintegrating, reducing or preparing fibrous materials, or mineral, chemical, oleaginous, or other substances. August 31

1887.

3848 C. J. Buhring. Filtering apparatus. September 21

8260 M. Lachman—From J. J. Rauer. Apparatus for automatically supplying gas to closed vessels at a regulated pressure. August 31

10393 E. W. Tucker. Hot air bridge walls for furnaces. August 27

10451 O. D. Orvis. Means for consuming smoke and gases in furnaces. August 31

10535 H. Davey. Air-compressing pumps. August 31

10723 R. Cunliffe and J. Lund. Apparatus for calcining, drying, roasting or carbonising materials, and extracting gases, spirits, or acids therefrom.

11035 R. Clayton. Construction of filters.

II.—FUEL, GAS AND LIGHT.

APPLICATIONS.

11367 G. Thew, J. Stansfield, and G. Long, Farnworth. Making illuminant gas and other chemical products from human excreta. August 20

---

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

11439 W. C. P. Asselbergs, London. Improvements in hydraulic mains for gas works. Complete specification. August 22

11440 W. C. P. Asselbergs. Improvements in apparatus for purifying or washing gas. August 22

11450 A. Eichelbrenner, London. Improvements in the manufacture of illuminating gas. August 22

11537 O. Bowen and A. S. Tomkins, London. Improvements in the manufacture of charcoal. August 24

11627 J. A. Walker, Farnham. An improved means of obtaining greater heat and generating steam more rapidly in boilers by the agency of liquid fuel. August 26

11783 J. Hall, London. Improvements in machinery for the manufacture of artificial fuel. August 30

12129 J. McEwen, London An improved double purifier or gas washer. Complete specification. September 7

12229 A. Kitson, Philadelphia. Improvements in carbureting gas lamps. Complete specification. September 9

12451 J. T. Williams, London. Improvements in treating anthracite coal, and in machinery or apparatus therefor. September 14

12481 W. H. Nevill, London. Improvements in artificial fuel for heating and gas producing purposes. September 14

12519 J. Orchard and H. Lane, London. Improvements in means and apparatus for producing and utilising heat and energy arising from the combustion of gases. September 15

12,560 A. Hill, Birmingham. Improvements in incandescent gas fires. September 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8163 R. Stone. Manufacture of fuel, and apparatus therefor. August 24

12340 A. G. Meeze. Apparatus for the manufacture of gas from fluid hydrocarbons. September 21

13578 H. H. Lake—From G. Godeffroy. Preparation of fuel. August 27

13637 R. Combret. Manufacture of blocks of artificial fuel. August 27

13752 W. M. Chinnery and H. Hill. Apparatus for inducing complete combustion of mineral oil, gases or smoke, to be used for heating or lighting. August 27

13922 W. H. Lindsay. Apparatus for moulding coal dust or small coal into solid blocks. August 24

13985 W. H. Lindsay. Manufacture of artificial fuel. Aug. 27

15007 C. S. Court, H. Veevers, and M. Schwab. Continuous process for the purification of coal gas from sulphur compounds, by which the sulphur is recovered. September 21

15621 B. H. Thwaite. Method of generating gaseous fuel, and apparatus therefor. September 21

1887.

8953 R. B. Avery. Method and apparatus for generating gas for illuminating, heating, and metallurgical purposes from liquid hydrocarbons. September 21

10102 A. J. Boult—From W. C. Shaffer. Application of the expansive power of heat, and apparatus therefor. September 14

11201 J. Tennent. Heating air and other fluids. September 21

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

11689 A. H. Allen and R. Angus, Sheffield. Improvements in the treatment of the oil or tar obtained by condensation from the gases of blast furnaces, gas producers and coke ovens, or by the distillation of bituminous shale, and in the utilisation of the products therefrom. August 29

11716 M. L. Honnay, London. A new or improved process for enriching pitch obtained by the evaporation of tars produced from coal. August 29

11805 S. Banner, Liverpool. Improvements in treating resins, oleo resins, gums, pitches, varnishes, bitumens, and other like substances. August 31

12090 Watson Smith, Manchester. The employment of the phenoloid bodies obtained from the tar or oil condensed from blast furnaces, coke ovens, or similar gases, or from the distillation of bituminous shale, in the manufacture of waterproofed indiarubber goods. September 7

COMPLETE SPECIFICATION ACCEPTED.

1887.

13929 H. Ellison and G. E. Davis. Method for distillation of coal tar, the oils from coke ovens, and other similar fluids. September 11

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

11879 C. D. Abel—From C. Wachendorff (of R. Koepp and Co.), Germany. Production of compounds of antimonic fluoride with alkaline fluorides and alkaline chlorides, and the application thereof and of known combinations of these substances to dyeing and printing. September 1

11880 C. D. Abel—From the Actiengesellschaft fur Anilin-Fabrikation, Germany. Process for the production of azo colouring matters. September 1

11976 J. Imray—From La Societé Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier and D. A. Rosenstiehl, France. Production of azoic colouring matters. September 3

11988 J. Dawson, Kirkheaton, and R. Hirsch, Huddersfield. The manufacture of rosaniline sulpho acid. September 5

11989 J. Dawson, Kirkheaton, and R. Hirsch, Huddersfield. The manufacture of a new alpha-naphtylamine-disulpho acid. September 5

12020 J. Imray—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier, and D. A. Rosenstiehl, France. Production of new azoic colouring matters. September 5

12285 E. Bentz, Manchester. Improvements in the manufacture and composition of oil compounds for dyeing and calico printing, and such like purposes. September 10

12355 J. Imray—From La Societe Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier and D. A. Rosenstiehl, France. Production of new tetrazoic colouring matters. September 12

12549 H. H. Lake—From Wirth and Co., agents for K. Oehler, Germany. Improvements in the manufacture of colouring matters. September 15

12667 C. S. Bedford, Liverpool. New or improved colouring matters, and process of manufacturing the same.

12692 J. Imray—From La Societe Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France, A. F. Poirrier and Z. Roussin. Production of colouring matters by combination of nitro-diazobenzoles and their analogues with isomers of naphthionic acid. September 19

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

14283 J. Anraheim. Methods of treating oxynaphthol and aniline or its homologues, obtaining certain products, and utilising the same in the manufacture of dyes. September 7

14625 J. H. Johnson—From the Badische Anilin and Soda Fabrik. Preparation of red colouring matters. September 17

15363 D. Stewart. Preparing grey and black colouring matters, to be applied to textile fabrics. September 21

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

11141 W. S. Archer, London. Improvements in machines for opening or separating and cleaning cotton or other fibrous material. August 22

11570 S. S. Bromhead—From U. C. Allen, United States. An apparatus for separating wool, silk, or other animal fibre, from vegetable fibre or other vegetable matter. Complete specification. August 25

11612 H. Martinz, London. Improvements in machinery for preparing or dressing textile fibres. Complete specification. August 26

11665 W. Nelson and E. Bowen, London. An improved machine for drying wool. Complete specification. Aug. 27

12365 J. Nasmith, Manchester. Improvements in and apparatus for combining fur or fur waste with fabrics made from cotton, wool, or other fibrous substances. September 13

12506 J. Fitton, J. Fitton, jun., and E. Fitton, Bradford. An improved method of and apparatus for carbonising or destroying vegetable matter contained in or mixed with woollen, silk, or other animal fibre or fabric. September 15

12709 W. Nelson and E. Bowen, London. An improvement in machinery or apparatus for drying wool. Complete specification. September 19

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11610 A. C. Henderson—From La Société Charles, Vignet, Sons & Co. Method and apparatus for dressing or sizing textile fabrics. August 31

1887.

9274 E. W. Serrell, jun. Process and machinery for reeling silk from the cocoon. September 21

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

APPLICATIONS.

11355 W. J. S. Grawitz, London. The preparation of cotton fibres for dyeing. August 19

11391 J. H. Gartside and J. Barnes, Manchester. Improvements in dyeing cotton and other vegetable fibres and yarns, and fibres composed thereof. August 20

11497 A. Graemiger, London. Processes of and apparatus for dyeing, scouring, bleaching, and otherwise treating yarn in cops. Complete specification. August 23

11525 J. Farran, Manchester. Improvements in bleaching certain materials. August 24

11812 J. Smith and P. W. Nicolle, Jersey. Improvements in bleaching cotton, flax, jute, rhea, esparto, and similar fibres and fibrous substances. August 31

11879 C. D. Abel—From C. Wachendorff (of R. Koepp and Co.), Germany. See Class IV.

12004 A. C. Henderson—From U. A. G. Herisson and G. Lefort, France. Improvements in bleaching vegetable fibres of all kinds, whether raw or manufactured. September 5

12075 B. Willcox—From the Farbenfabriken Vormals, F. Bayer and Co., Germany. A new process or means for producing azo colour upon animal or vegetable fibres or fabrics in printing or dyeing. September 6

12144 T. F. Naylor, Kidderminster. Improvements in dyeing yarns. September 8

12283 M. Ashworth and R. Wild, Rochdale. Improvements in apparatus or machinery for washing, scouring, or bleaching fibres, fibrous materials, and textile fabrics. September 10

12358 T. Sampson and F. H. Jealous, London. Improvements in the dyeing of yarn and other fibrous materials, and in means or apparatus employed therein. Complete specification. September 13

12502 J. Birtwistle, Manchester. Improvements in the printing of textile fabrics. September 15

12522 T. Skene and L. Devallee. Improvements in machines for dyeing wool and other textile materials. September 15

12602 C. T. Clegg, H. A. Clegg, and F. Lee, Manchester. Improvements in apparatus for dyeing wool, cotton, silk, or other similar fibrous material. September 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11981 A. Hodgkinson. Cleansing composition for use in bleaching cotton and linen fabrics or yarns, etc. August 31

13814 A. Aykroyd, W. E. Aykroyd, and J. Smith. Aniline black dyeing or printing processes for obtaining a fast aniline black in textile fibres and fabrics. September 14

1887.

4953 A. Brin and L. Q. Brin. Bleaching fibrous substances for paper making. September 10

VII.—ALKALIS, ACIDS AND SALTS.

APPLICATIONS.

11449 J. Clark, London. Improvements in obtaining chloride of aluminium, etc. August 22

11456 W. S. Squire, London. See Class I.

11492 H. H. Lake—From A. Kayser, H. Williams, and A. B. Young, United States. Improvements relating to the production of caustic alkali carbonates of the alkaline metals, muriatic acid, and other substances. Complete specification. August 23

11493 H. H. Lake—From A. Kayser, H. Williams, and A. B. Young. An improved method or process of producing silicate of sodium or of potassium. Complete specification. Aug. 23

11494 H. H. Lake—From A. Kayser, H. Williams, and A. B. Young. An improved method or process of producing muriatic acid. Complete specification. August 23

11500 C. J. E. de Haën, Liverpool. Improvements in the manufacture and application of the compounds of fluoride of antimony with the combinations of the chlorides of sodium, potassium, and ammonium, and phosphates of soda, potash, and ammonia. Complete specification. August 23

11653 F. P. E. de Lalande, London. Improvements in the manufacture of caustic soda and potash. August 27

11799 R. Wyllie, Liverpool. Improvements in and connected with apparatus for distilling ammoniacal liquors. August 31

11821 T. Schloesing, Paris. Extraction of chlorine from solutions of chloride of magnesium. August 31

11846 G. E. Davis, Manchester. An improved method of manufacturing alkalis. September 1

12219 W. McElroy and H. Connett. See Class I.

12674 W. L. Wise—From G. M. Tauber, Saxony. Process for the manufacture of sodium-ammonium-sulphite and converting the same into sodium sulphite and sodic hydrate. September 19

12700 S. Pitt—From V. Ragosine and P. Dvorkovitch, Russia. Method of producing anhydrous sulphuric acid and its monohydrate, and of utilising for this purpose the acid residues of petroleum production and other, as also sulphates of all metals. September 19

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10868 J. Lea and H. R. Hammond. See Class X.

12480 F. H. Gossage, T. T. Mathieson, and J. Hawliczek. Treatment of sulphate of sodium for manufacture of sulphide of sodium therefrom, and apparatus therefor. September 7

13286 A. Frank. Treatment of spent lyes used in manufacture of cellulose, by means of sulphites, for recovery of sulphurous acid therefrom, and utilisation of said lyes after such treatment. September 17

13389 E. Solvay. Continuous furnace for the production of chlorine. August 31

13762 W. Bramley and W. P. Cochrane. Manufacture of hydrate carbonate of magnesia and other products produced herein. September 3

14217 J. B. Hannay. Manufacture of sulphuric acid. September 10

14441 W. Burns. Manufacture of sulphuric acid under high pressure with agitation, and apparatus therefor. August 31

14673 E. Hermite, E. J. Patterson, and C. F. Cooper. Apparatus for preparation of bleaching solutions by electrolysis. September 17

14711 J. Simpson and E. W. Parnell. Apparatus for treatment of sulphuretted hydrogen for the separation of sulphur or the production of sulphurous acid. September 21

15182 E. P. Alexander—From E. J. L. Delsol. Obtaining mother-liquors free from magnesium salts in the manufacture of carbonate of potash by means of the double carbonate of potash and magnesia. September 21

15352 W. Burns. Manufacture of bichromate and carbonate of soda by the ammonia process, and apparatus therefor. September 14

VIII.—GLASS, POTTERY AND EARTHENWARE.

APPLICATIONS.

11495 A. J. Boult—From F. Czech, Austria. Improvements in decorating ceramic ware. Complete specification. Aug. 23

11513 J. S. Williams, Brierley Hill Glass Works. Improvements in frosting the surfaces of flint and coloured glass ware. August 24

11906 J. Budd, London. Improvements in the crystallisation of glass. September 2

12001 J. Miller and The Sowerby's Ellison Glass Works, Limited, London. Improvements in polishing cut glass of every description. September 5

12546 A. D. Brogan, J. French, and J. Craig, London. Improvements in and connected with glass annealing kilns. September 15

12566 C. G. Warne, Weston-super-Mare. Improvements in pottery kilns for the purpose of economising fuel and equalising the burning of the goods. September 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12496 W. Horn and R. Bell. Shears used in the manufacture of glass bottles. September 17

14216 A. M. Clark—From E. Weis. Process for cutting very thin parts on glass articles. September 14

14288 G. F. Chance. Machinery employed in manufacture of sheets of rolled glass. August 31

14380 A. D. Brogan and A. M. Malloch. Manufacture of chequered glass, and apparatus therefor. September 7

14727 H. M. Ashley. Manufacture of bottles, etc. September 14

16613 J. Northwood. Treating the glass cullet known as blacks. September 21

1887.

87 W. H. Hales. Machinery for making pottery ware. August 21

10874 A. J. Boult—From P. Sivert. Glass furnaces. Sept. 10

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

11509 H. Warrington and W. W. Howlett, Hanley. Improvements in bricks and other blocks for building purposes. August 24

11937 J. Homan, London. Improvements in the construction of fireproof floors. September 2

11996 S. G. Rhodes, Leeds. Making bricks. September 5

12271 J Davies, Manchester. Improvements in the construction of brick kilns. September 10

12503 E. Winsor, F. Winsor, and J. Winsor, Manchester. Improved method of treating clay or gypsum, and apparatus therefor. September 15

12524 G. J. Snelus, W. Whamood, and T. Gibb, London. An improved preparation or manufacture of cements. September 15

12525 G. J. Snelus, W. Whamond, and T. Gibb, London. Improvements in the preparation or manufacture of cements. September 15

12526 G. J. Snelus, W. Whamond, and T. Gibb, London. Improvements in the manufacture of cements. September 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11303 E. Larsen. See Class X.

13981 W. H. Lindsay. Apparatus for moulding bricks or blocks. September 14

14674 W. Scott, J. C. Swan and H. Smith. Manufacture or treatment of Portland and other hydraulic cements. September 14

15012 H. Macevoy, H. Holt, L. White, and W. Wilders. Manufacture and burning of Portland cement. September 14

1887.

10898 E. Keirby. Compound or cement for making and renovating asphalte walks, protecting masonry, and analogous purposes. September 17

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

11432 G. French, London. An improved method of blasting in coal mines and in other places, and in materials to be used therein. August 22

11449 J. C. Clark. See Class VII.

11474 P. C. Gilchrist, London. Improvements in the manufacture of steel and ingot iron by the basic process. Complete specification. August 23

11478 L. L. Lefevre, jun.—From C. Payen, United States. Improvements in the manufacture of crystallised metal, and in articles made thereof. August 23

11510 F. Fenton and R. J. Partridge—From J. Woolford, France. Improvements in plant, apparatus, furnaces, or retorts for extracting auriferous and other metallic ores, slags, cinders, or wastes. August 24

11516 E. Cope and A. Hollings, Liverpool. Improvements in hollow steel shafting, and in the manufacture of the same. August 24

11532 G. Gatheral, London. Improvements in the treatment of ores for the extraction of copper therefrom, or of ore residues and the like, for the elimination of copper or other impurities. August 24

11556 J. McCann, Millom. The improvement of blocks and tuyeres connected with blast furnaces. August 25

11571 R. E. Shill and A. Martin, London. Improvements in hardening or chilling the face of armour and other plates and projectiles. August 25

11613 F. A. Herbertz, London. Improvements in cupola smelting furnaces. Complete specification. August 26

11672 M. M. Bair, London. Improvement relating to the volatilisation of lead, antimony, and other substances, and to the condensation of the resulting vapours. August 27

11733 J. E. Bennett, Manchester. Improvements in the treatment of metallic chlorides for the extraction of metals therefrom. August 30

11797 A. M. Crossley, Glasgow. Improvements in preparing ferruginous material for smelting. August 31

11862 C. F. Clark and J. Sanders, London. Improvements in preparing moulds for casting hollow-ware, and in apparatus employed therein. September 1

11868 J. Gilligan, London. Improvements in the working up of scrap iron and steel, either separately or together in a puddling furnace. September 1

11898 N. Arthur, Heaton. Improved method and apparatus for bending angle, tee, and other sections of bars. Sept. 2

11900 A. J. Shannon, London. Improvements in the extraction of antimony from its ores. September 2

11928 J. W. Swann, London. Improvements in apparatus for indicating the presence of fire-damp in coal mines or other places. September 2

11945 H. A. Rowland, Manchester. Improvements in the casting of metals. September 3

12032 L. B. Atkinson, H. W. Ravenshaw, and F. Mori, Halifax. Improvements in machines for cutting, boring, or drilling coal or other minerals. September 6

12042 W. P. Thompson—From C. Kellogg, United States. Improvements in machines for rolling seamless tubes, pipes, or other hollow articles from hollow ingots. Complete specification. September 6

12111 W. P. Thompson—From E. Dumas, Paris (agent for Bickford, Smith & Co.) Improvements in electric fuses for mines. September 7

12162 C. Humfrey, Liverpool. Improvements in or appertaining to the manufacture of sodium. September 8

12210 J. T. King—From H. Kennedy, United States. Improvements in connection with hot blast stoves and furnaces. Complete specification. September 9

12269 G. Hardy, Abram, Lancashire. An improved miners' safety lamp. September 10

12272 G. Siddell, Sheffield. An improved process in iron and steel. September 10

12277 A. J. Shannon, London. Improvements in the treatment of zinc ores. September 10

12332 S. Pearson, A. W. Turner, and W. Andrews, Birmingham. A new process of extracting aluminium from minerals, and also making aluminium alloys therefrom. Complete specification. September 12

12346 J. D. Ellis, London. Improved method of making iron or steel castings. September 12

12347 T. J. Tresidder, London. Improved means for hardening metal. September 12

12353 H. Le Neve Foster, London. An improved fire-resisting compound, especially suitable for forming the stoppers and nozzles used in steel melting operations and other similar purposes. September 12

12378 B. H. Thwaite, Liverpool. An improved pneumatic steel process, and plant therefor.

12458 H. Bird, Liverpool. Treating the residual spent iron liquors resulting from the manufacture of copper from burnt cupreous sulphur ores to obtain a certain oxide of iron therefrom, and apparatus to be used therefor. September 14

12486 O. M. Thowless, London. Improvements relating to the production of sodium and potassium, and to apparatus therefor. Complete specification. September 14

12540 A. B. Cunningham, London. Improvements in the manufacture of sodium and potassium, and in apparatus therefor. September 15

12575 A. Feldman, London. Improvements in the production of aluminium and alloys of aluminium. September 15

12590 H. Lane, London. Improvements in shaping, forming and manipulating metals. September 16

12616 J. Thomas, Middlesbrough-on-Tees. Improvements in ingot moulds. September 17

12683 F. M. A. Laurent-Cely, London. Improvements in the manufacture of spongy lead suitable for electrical accumulators. September 19

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10868 J. Lea and H. R. Hammond. Operating on zinc ore for producing chlorine and zinc, and utilising the said zinc for coating metals. August 31

11249 W. S. Squire and S. C. C. Currie. Obtaining zinc in metallic form from alkaline solutions of zinc oxide. September 7

11303 E. Larsen. Manufacture of furnace slag and of cement partly made therefrom. September 10

12011 T. Blackmore. Metallic chill core. September 11

12362 C. J. Sandahl, J. Birchall, and J. Musson. Manufacture of iron and steel, and blast furnaces employed therein. August 27

12363 C. J. Sandahl, J. Birchall, and J. Musson. Manufacture of iron and steel. August 27

12630 W. S. Squire and S. C. C. Currie. Obtaining metallic zinc from its ores. September 7

12729 G. M. Edwards. Process and apparatus for treating, dressing, and cleaning tin and other mineral ores. August 27

13503 E. Wheeler. Production of metal bodies or ingots. August 31

13562 P. M. Justice—From W. B. Spear. Coating metal sheets with other metal. August 27

13680 B. C. Tilghman. Drawing iron and steel bars through dies to produce a smooth surface suitable for shafting. August 21

13920 T. Nordenfelt. Manufacture of iron and steel castings. August 27

14061 J. B. Hannay. Obtaining gold from refractory ores, etc. August 21

14169 T. Nordenfelt—Partly from C. G. Wittenström, E. Faustman, and P. Ostberg. Bessemer converters, and manufacture of castings thereby. September 10

14220 R. W. Lindsay and W. Darwen. Manufacture of tubes of copper or copper alloys. August 31

14385 E. Patterson and W. H. Strype. Miners' safety lamps. September 14

14407 O. M. Thowless. manufacture of aluminium chloride, and extraction of aluminium therefrom. September 21

14568 A. Howat. Electric safety lamps. September 10

14903 J. G. Cranston. Machinery for drilling rock, etc. September 14

14974 M. Settle. Electric safety lamps for use in mines. September 21

15001 A. M. Clark—From H. A. Brustlein. Process and apparatus for hardening shells and other steel articles. September 10

15206 E. C. Molloy. Apparatus for amalgamating gold and other precious metals. September 21

15476 A. Wilson. Manufacture of compound armour plates. September 3

1887.

2602 C. A. Burghardt and W. J. Twining. See Class XVIII. August 24

9471 J. B. D. Bolton. Process and apparatus for casting metallic ingots in a sectional mould. September 7

10100 W. J. Wilder. Process of coating metals. September 3

10815 W. P. Thompson—From M. G. Farmer. Process and apparatus for procuring aluminium. September 17

XI.—FATS, OILS AND SOAP MANUFACTURE.

APPLICATION.

12181 W. H. Gilruth, London. Improvements in apparatus for extracting oil or juice from seeds, nuts, fruits or leaves of plants, or any analogous substances. September 8

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11981 A. Hodgkinson. See Class VI.

14835 F. T. Archer, G. W. Hardy, and F. J. Archer. Lubricating composition. September 7

1887.

10783 J. Sears. Compound preparation of cotton seed oil. September 7

XII.—PAINTS, VARNISHES AND RESINS.

APPLICATIONS.

11805 T. Banner, Liverpool. See Class III.

12631 H. J. Allison—From G. W. Barker, United States. Improvements in paints and paint compounds. Complete specification. September 6

12338 W. Fordyce, Glasgow. An improved anti-fouling composition for ships' bottoms and other submerged surfaces. September 12

12388 E. C. Atkinson, London. Improvements in and machinery for packing paste blacking and other similar semi-liquid matters. September 13

12632 J. C. Lyman—From J. H. Lyman, United States. An improvement in paint. September 17

COMPLETE SPECIFICATION ACCEPTED.

1886.

11889 F. M. Lyte. Manufacture of pigments. September 17

XIII.—TANNING, LEATHER, GLUE AND SIZE.

APPLICATION.

12,396 J. Pujos, London. The manufacture of leather from rabbit skins. September 13

COMPLETE SPECIFICATIONS ACCEPTED.

-1887.

9193 H. H. Lake—From A. M. Bowers. Machines for softening and otherwise treating leather. August 21

10121 J. W. Vaughan. Machines for unhairing and green shaving hides and skins.

XV.—SUGAR, GUMS, STARCHES, ETC.

APPLICATIONS.

11393 O. Bowen and J. Cobeldick, London. An improved deodorising, decolourising and filtering medium. August 20

12596 C. H. J. Franzen, London. Process for manufacturing white, lump or loaf sugar directly from boiled refinery mass. Complete specification. September 16

12597 C. H. J. Franzen. Process and apparatus for treating raw, clarified or perfectly white sugar masses in loaf forms by means of the centrifugal machine. Complete specification. September 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

17041 R. Campbell—From J. Foster and J. Campbell. Triple effet evaporating vacuum pans, for boiling sugar and other evaporating purposes. September 14

1887.

10157 J. T. Griffin—From R. J. Henderson. Indiarubber compositions. September 17

10458 J. T. Griffin—From R. J. Henderson. Manufacture of soft or spongy material from rubber compound. September 7

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

11376 F. G. Burton and T. S. Coleman, Burton-on-Trent. Cleaning malting tiles, and removing therefrom sediment or deposit formed therein by barley or other grain and malt whilst in the course of steeping and drying, and also for cleaning and removing coatings formed on brewing and other coppers after boiling, and also the glutinous and other substances from refrigerators, after use in cooling process of beer and other liquors. August 20

11584 A. J. Boult—From B. Bruel. See Class XXII.

12057 A. G. Brookes—From C. G. P. de Lavel and A. Bergb, Sweden. Improvements in purifying yeast. September 6

12329 W. G. Hicks, Ramsgate. Improving furnaces used for drying the barley in the process of making malt, for drying hops and other similar purposes. September 12

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12291 E. Manbre. Compounds for the manufacture of ale, stout, porter, lager, etc., and apparatus for making said compounds. September 3

14468 E. Piot. Distilling apparatus, applicable to the concentration and rectification of alcoholic and other liquids. September 10

14873 H. H. Lake—From M. Hanford and C. C. Hanford. Cooling of liquids, and apparatus therefor. August 31

1887.

8260 M. Lachmon—From J. J. Rauer. Apparatus for automatically supplying gas to closed vessels at a regulated pressure. August 31

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, ETC.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

11927 A. McDougall, jun., London. Improvements in the manufacture or preparation of concentrated extracts or essences of tea, coffee and the like with cream or milk. September 2.

12065 H. H. Lake—From J. H. Stebbins, jun., United States. An improved food compound. Complete specification. September 6

12431 H. Stollwerck and L. Stollwerck, London. Improvements relating to the treatment of cocoa to facilitate the transport thereof, and for other purposes. Complete specification. September 13

12520 J. M. Mitchell, Chicago, United States. New and valuable improvements in the preservation of perishable articles of food, and other perishable matter, by means of ozone or other gases. September 15

12595 W. H. Beck—From E. A. Dexmier, France. A new or improved preparation of coffee, and process for manufacturing the same. September 16

B.—SANITARY CHEMISTRY.

11367 G. Thew, J. Stansfield, and G. Long. See Class II.

11185 J. H. Barry, London. Improvements in treating and purifying sewage, the same being applicable for other disinfecting purposes. August 23

11534 T. M. J. Truchelut and J. N. Truchelut, London. A new or improved process and apparatus for the treatment of sewage and other matters, for extracting or neutralising ammonia and sulphur compounds. August 24

11947 G. Liscoe, London. An improved method and means of separating the solids from the fluids of sewage matters. September 3

12212 F. W. Durham, London. An improved construction of furnace for burning town refuse. September 9

C.—DISINFECTANTS.

11393 O. Bowen and J. Cobeldick, London. An improved deodorising, decolourising, and filtering medium. August 20

12029 J. Bennett, London. A new disinfectant. September 5

12222 R. V. Tuson, London. Improvements in the preparation of materials to be used as disinfectants, deodorisers, and antiseptics, as well as for the destruction of parasites infesting man and the lower animals, and for similar uses. September 9

12392 G. Van Overbeck de Meyer, London. Improvements in apparatus for disinfection. September 13

12483 J. Bennett, Goole. A new disinfectant. September 11

COMPLETE SPECIFICATIONS ACCEPTED.

A.—CHEMISTRY OF FOODS.

1886.

13731 E. Terrant. Manufacture of biscuit bread. August 27

13955 H. Stockman. Curing articles of food, and disinfecting. September 3

1887.

10915 H. H. Lake—From H. C. Andrews. Apparatus for drying or curing fruit, tobacco, etc. September 17

10917 H. H. Lake—From T. C. Oakman. Apparatus for drying or curing fruit, tobacco, etc. September 17

B.—SANITARY CHEMISTRY.

1886.

15222 W. Burns. Purifying sewage and other foul liquids, and making oil, alkali, and cement from sewage precipitate, and apparatus therefor. September 21

XVIII.—ELECTRO-CHEMISTRY.

APPLICATIONS.

11369 C. Gauzentès, Bradford. Improvements in electric batteries. August 20

11390 J. S. Stevenson, London. Improvements in the manufacture of elements or plates for secondary batteries or electrical accumulators. August 20

11443 J. S. Sellon, London. Improvements in secondary batteries or electrical accumulators. August 22

11502 E. F. H. H. Lauckert, London. Improvements in dynamo-electric and electro-dynamic machines. August 23

11513 H. Tudor, Liverpool. Improvements in electrodes for electric accumulators or secondary batteries. August 24

11923 C. L. R. E. Menges, London. Improvements relating to the manufacture of plates or electrodes for primary or secondary electric batteries, and to apparatus therefor. September 2

12017 P. L. Verchère, London. Improvements in the manufacture of carbons for voltaic batteries and certain other electrical apparata. September 5

12175 W. B. Adams, London. Improvements in secondary batteries. September 8

12203 T. L. Hemming, Birmingham. Improvements in dynamo-electric machines. September 9

12252 R. P. Sellon, London. Improvements in dynamo-electric machines. September 9

12528 J. A. Timmis, London. Improvements in the construction of secondary batteries. September 15

12542 T. C. Lewis, London. Improvements in electrical storage batteries. September 15

12676 W. T. Goolden and L. B. Atkinson, London. Improvements in dynamo-electric generators and motors. September 19

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12818 W. W. Beaumont. Secondary batteries. August 31

13618 W. R. Johnston. Manufacture of carbons for electrical and other purposes. August 24

13712 A. M. Clark—From The Electrotechnische Fabrik Cannstatt. Dynamo electric machines. August 27

14563 J. S. Sellon. Secondary batteries. September 14

14757 W. Lahmeyer. Dynamo electric machine. September 17

14765 C. Lever. Dynamo-electric machines and electric motors. September 17

16810 T. Goodman—From C. Gasner, jun. Galvanic elements.

1887.

990 S. W. Maquay. Means for feeding electric batteries, and for removing the plates therefrom. September 7

2662 C. A. Burghardt and W. Twining. See Class X. August 24

10217 J. Serson and J. O. Whitten. Galvanic batteries. August 24

11188 H. H. Lake—From W. E. Case. Conversion of chemical energy into electrical energy, and apparatus therefor. September 17

11189 H. H. Lake—From W. E. Case. Apparatus for the conversion of heat into electrical energy. September 17

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

11610 J. E. Warren and F. A. Cloudman, London. Improvements in means or apparatus for effecting the recovery of chemicals from spent liquors of pulp digesters. Complete specification. August 26

11735 J. Baldwin, King's Norton. An improved mode of pressing paper whilst in the process of manufacture, securing an equal surface on both sides of the paper, and obtaining the conditions produced by hand-pressing. August 30

12642 R. Squire, London. Improvements in apparatus for the manufacture of paper. September 17

12686 R. Ellis, London. Improvements in the manufacture of pulp for making kamptulicon, linoleum, and paper. September 19

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

13827 B. Makin. Fitting cylinders with blades used in macerating materials for pulp for the manufacture of paper, millboards, etc. August 27

1887.

6171 F. Voith. Machines for the manufacture of paper pulp. September 17

10306 G. R. Gill. Utilisation of paper, paper board, pulp, or any preparation of which paper forms the base, for the manufacture of geometric models. August 31

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

11617 O. Imray—From the Society of Chemical Industry, Switzerland. Manufacture of the ethylether of a new acid. September 3

14618 O. Imray—From the Society of Chemical Industry, Switzerland. Manufacture and treatment of a compound of phenylhydrazine, with a new ethylether. September 7

1887.

7261 C. T. Arnold—From C. W. Arnold. A dental anodyne, or local anæsthetic. September 3

XXI.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

11658 E. Edwards—From R. Sjöberg, Sweden. Improvements in explosives. Complete specification. August 27

12297 W. T. Chamberlain, London. A new method of enclosing high and sensitive explosives in shells and other projectiles. September 10

12424 E. D. Muller, London. Improvements in explosive compounds. September 13

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

14803 Sir F. A. Abel. A manufacture of smokeless explosive. September 14

1887.

6071 F. D. Banister and W. Stroudley. Fog signal apparatus for railways. September 17

XXII.—GENERAL ANALYTICAL CHEMISTRY.

APPLICATION.

11584 A. J. Boult—From B. Bruel. Improved apparatus for testing alcohol. August 25

Printed and Published by EMMOTT & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.
LONDON OFFICE, for the Sale of Copies and Receipt of Subscriptions: 6, York Street, Covent Garden

THE JOURNAL
OF THE
Society of Chemical Industry:
A MONTHLY RECORD
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 10.—Vol. VI. OCTOBER 31, 1887. Non-Members 30/- per annum; Members 21/- per Set; Single Copies 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.

COUNCIL FOR YEAR ENDING JULY, 1888.

President: Prof. James Dewar, F.R.S.

Vice-Presidents:

Prof. F. Clowes, D.Sc.
Sir J. Neilson Cuthbertson.
David Howard.
Dr. Ferdinand Hurter.
Ivan Levinstein.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
Prof. W. A. Tilden, F.R.S.
John Williams.
Philip J. Worsley.

Ordinary Members of Council:

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J. Rowan.
Dr. Edwd. Schunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

With Sixteen Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, 20, Avenue Road, Regent's Park, N.W.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

NOTICES.

Notice is hereby given that the numbers for January, 1882, 1883, and 1886, and February, 1886, are exhausted, and no orders for those copies can be executed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January, 1882 and 1883, at the following prices:—January, 1882, 5s.; January, 1883, 2s. 6d. Members possessing odd copies of these numbers are particularly requested to communicate at once with Mr. Cresswell.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

CHANGES OF ADDRESS.

T. Akitt, l/o Tirhoot; 3, Victoria Road, Lenzie, N.B.

Jas. Angus, l/o Lugar; Thorncliffe Collieries, Chapeltown, Sheffield.

James Armour, l/o Bothwell Street; Clippens' Oil Co., Limited, 27, Exchange Square, Glasgow.

W. H. Aubrey, l/o Plumstead; 32, Ashmead Road, St. John's, S.E.

J. A. Bradburne, l/o Northwich; Quince Street, Geddes, Syracuse, N.Y., U.S.A.

Dr. L. Claisen, l/o Marsstrasse; Sophienstrasse, 6/0, München, Bavaria.

H. D. Dupee; Journals to Walpole, Mass., U.S.A.

G. J. Hamlen, l/o Silvertown; 10, Willowbank Crescent, Glasgow.

J. Wm. James, l/o Cardiff; Aylmer House, Weston-super-Mare.

J. Lorimer, l/o Hargrave Park Road; Britannia Row, Islington, N.

T. M. Macdonald; Journals to Walilabo Estate, St. Vincent, West Indies.

H. T. Mannington, l/o Liverpool; Pentre, near Flint, North Wales.

J. Ostersetzer, l/o Castleknock; Balcarras House, Serpentine Avenue, Ballsbridge, Dublin.

Prof. W. Ramsay, l/o Bristol; University College, Gower Street, London, W.C.

Wm. Ray, l/o Leeds; School of Science, Kidderminster.

H. H. Robinson, l/o Cirencester; 12, Montpelier Row, Twickenham.

W. T. Scott, l/o Stratford; 11, Cromartie Road, Hornsey Rise, N.

C. Sevin; Journals to "Strathmore," 72, Central Hill, Upper Norwood, S.E.

F. P. Siddall, l/o New Barnet; Park Side, Barnet Common, Herts.

F. Napier Sutton, l/o Gordon Square; 22, Hartham Road, Holloway, N.

Chas. Thompson, l/o Leighton Crescent; 15, Patshull Road, Kentish Town, N.W.

G. M. P. Vary, l/o Edinburgh; General Post Office, San Francisco, Cal., U.S.A.

C. Wightman, l/o Fenchurch Street; 1, Fenchurch Avenue, London, E.C.

P. J. Worsley; Journals, etc., to Rodney Lodge, Clifton, Bristol.

A. Wuth., l/o Ramsbottom; 11, Dambachthal, Wiesbaden, Germany.

CHANGES OF ADDRESS REQUIRED.

F. Nettlefold, l/o Sterndall Road, West Kensington.

M. W. Wiley, l/o 1, Bell Terrace, West Hartlepool.

LIST OF MEMBERS ELECTED, 28th OCTOBER, 1887.

Thomas Bailey, 25, High Street, Hull, seed crusher.

John Blair, 18, Old Mill Road, New Hendon, Sunderland, tar distiller

John Clark, 80, Great Brook Street, Birmingham, metallurgist.

W. H. Constable, Hale Bank, Widnes, Lancashire, analytical chemist.

Samuel Dalziel, Smyrna, Asia Minor, chemist.

Bennett F. Davenport, A.M., M.D., 161, Tremont Street, Boston, Mass. U.S.A., State analyst.

William Dixon, 102, Spring Street, Bury, Lancashire, science master.

Alexander Ellis Ford, 4, Orme Square, Hyde Park, W., chemical manufacturer.

J. R. P. Goold, 68 and 70, Hop Exchange, Southwark Street, S.E., chemical manufacturer.

J. C. Harvey, Eccleston Hall, Prescot, Lancashire, brewer.

John Heaton, 711, Rochdale Road, Manchester, manufacturing chemist.

S. C. Hignett, 66, Whitechapel, Liverpool, tobacco manufacturer.

G. H. Holden, Langley Place, Victoria Park, Manchester, manufacturing chemist,

Joseph Jackson, Ash Bank, Rudheath, Northwich, alkali manufacturer.

Cavalier H. Jouet, Roselle, Union Co., N.J., U.S.A., technical chemist.

Robert King, 115, Wellington Street, Glasgow, chemical manufacturer and merchant.

Sir James King, 12, Claremont Terrace, Glasgow, chemical manufacturer and merchant.

Vivian B. Lewes, Royal Naval College, Greenwich, S.E., assistant professor of chemistry.

Chas E. Munroe, Torpedo Station, Newport, Rhode Island, U.S.A., chemist.

H. T. Pentermann, 51, Clifton Crescent, Peckham, S.E., chemist.

Arthur J. Shannon, c/o Syme & Co., Singapore, mining engineer.

Albert Tarn, 1, Darnley Road, Monument Road, Birmingham, technical chemist.

J. F. Tristram, 8, Castle Street, Northwich, chemist.

Stuart Tyzack, Brockett House, Montgomery Road, Sheffield, steel manufacturer.

Fred. Young, Tonge Lane, Middleton, Manchester, chemist.

Death.

Charles Moseley, Grangethorpe, Rusholme, Manchester—October 1.

London Section.

Chemical Society's Rooms, Burlington House.

Chairman: David Howard.

Committee:

Sir F. A. Abel.
H. E. Armstrong.
W. Lant Carpenter.
W. Crowder.
W. J. Dibdin.
C. Graham.
S. Hall.
C. C. Hutchinson.
R. Messel.
B. E. R. Newlands.
B. Redwood.
T. Royle.
John Spiller.
Wm. Thorp.
C. R. Alder Wright.

Hon. Local Sec. and Treasurer: Thos. Tyrer, Garden Wharf, Church Road, Battersea, S.W.

The meetings of the London Section will be held on the first Monday in each month.

SESSION 1887–88.

Prospective Arrangements.

Nov. 7.—Mr. C. T. Kingzett, F.I.C., F.C.S., "Note on the Comparative Antiseptic Action of Chlorides, Nitrates and Sulphates."

" Discussion on Mr. John Ruffle's Paper in July Number of Journal (1887), on "The Correct Analysis of Superphosphates, Plain and Ammoniated."

Dec. 5.—Professor Dewar, M.A., F.R.S. (President of the Society), "The New Weldon-Pechiney Process for the Manufacture of Chlorine from Chloride of Magnesium."

Communications to be addressed to the Local Secretary.

Communications.

REPORT ON SECTION III. OF THE MANCHESTER ROYAL JUBILEE EXHIBITION.—THE CHEMICAL AND ALLIED INDUSTRIES.

BY WATSON SMITH,

Lecturer in Chemical Technology in the Victoria University, etc.

Before proceeding to describe some illustrations of the results of chemical research of more modern date having a direct bearing on the chemical industries, a report on this, probably the most complete exhibition of objects illustrative of the progress, advance, and present position of the chemical industries that has ever been brought together, with a description of certain interesting relics of chemical and physical discovery that have had the most important influence on the growth of chemical science, and hence on the development of chemical industry, will be desirable. To commence with scientific celebrities belonging to Manchester, there is a most interesting selection of the apparatus employed by John Dalton in his classical researches. Here one may see how the most homely utensils are made useful for doing the highest class of scientific work, and how so humble an instrument as an old-fashioned penny earthen inkpot or a soda-water bottle may be rendered classical. The MS. of the "Principles of Chemistry," with the original table of atomic weights as first determined by Dalton, will be to chemists objects of the deepest interest. Dr. J. P. Joule, F.R.S., has lent for exhibition the very apparatus with which he determined the mechanical equivalent of heat. It consists of a small iron cylinder furnished with a central shaft and agitating apparatus and a cover fitted with holes for the end of the shaft and for a thermometer with which to measure the rise of temperature produced in the conversion of mechanical energy into heat. The important result attained by Joule he expressed thus:—The actual quantity of heat developed by friction is dependent simply on the amount of force expended, without regard to the nature of the substances rubbed together, and the numerical conclusion deduced was that the quantity of heat capable of raising the temperature of 1lb. of water by 1° F. requires for its evolution the expenditure of a mechanical force adequate to lift 772lb. one foot. It may be added that a good sketch of Joule's apparatus, and description of his method of using it, is given in the *Phil. Trans.*, 1850, Part I.

Here may be seen the very first lamps constructed by Davy, whilst patiently feeling his way towards a light which could be used with safety in our coal-mines. Four or five of the Davy safety lamps in various stages of construction are exhibited.

Also Davy's chemical balance, an unwieldy looking object compared with the delicate instruments of to-day, is shown.

Perhaps the greatest discovery made by Davy was that recorded in the *Phil. Trans.* for 1808, when he succeeded in decomposing the alkalis potash and soda by electricity, producing the respective alkaline metals, potassium and sodium. A portion of the very galvanic battery used is shown, together with the laboratory note-book, which is opened at the page in which the record may be read in Davy's handwriting. Sodium is now an article of commerce, and fine specimens of it may be seen at Stand 804, just opposite, shown by the Magnesium Metal Company, Limited. It is chiefly used in the manufacture of aluminium.

One of Faraday's greatest discoveries was that of the possibility of liquefying certain gases, up to that time regarded as permanent, by means of strong pressure.

Specimens of liquefied gases are shown in sealed tubes. These are hydrochloric acid, cyanogen, ammonia, arseniuretted hydrogen, hydrobromic acid, chlorine, chlorine and sulphuric acid, sulphuretted hydrogen and hydriodic acid.

Faraday's laboratory note-book, which is also exhibited, is opened at the place where this discovery is recorded.

Coal-tar distillers, gas manufacturers, and aniline dye manufacturers will be greatly interested to see the very first specimen of benzene as it was originally isolated and prepared by Faraday. It was called by him "bicarbide of hydrogen," the old formula of benzene being $C_{12}H_6$.

The other specimen, also contained in a sealed tube, is one of carbon tetrachloride prepared by him.

A plate of earthenware is shown on which characters have been inscribed, burnt in and glazed; the characters are in the handwriting of the great chemist, Berzelius.

Passing on to those exhibits illustrating chemical research, it may be noted that some of the discoveries which have had the most important influence on the development of chemical industry were made *accidentally*, during investigations in quite other directions.

SIR HENRY E. ROSCOE, M.P., F.R.S. (No. 741)—This exhibit comprises a collection of specimens of pure vanadium and tungsten, with various compounds of these rare metals, illustrating Roscoe's researches. Roscoe found vanadium in deposits near Alderley, and when subsequently John Lightfoot showed the important influence this metal was capable of exerting, even in mere traces, in printing aniline black, Roscoe suggested to Mellor of Patricroft, the industrial preparation of vanadium compounds for the use of the printer of aniline black. Mellor procured a quantity of the raw material from Mottram, near Alderley, and manufactured vanadium compounds for a considerable time. The specimens exhibited illustrate a very completely worked-out research in inorganic chemistry.

DR. EDWARD SCHUNCK, F.R.S. (No. 741A).—The specimens exhibited consist for the most part of natural colouring matters. Some of them, it will be observed, are colourless, or only slightly coloured; these are chromogens—*i.e.*, bodies which, when suitably treated, yield colouring matters. As an example of a chromogen we may take orcin, a colourless crystallised substance contained in various species of lichen, which, by the combined action of air and alkalis, yields orcein, the colouring matter to which orchil and litmus owe their dyeing properties. Orcin was discovered by Robiquet, an eminent French chemist. Dr Schunck many years ago discovered lecanorin, a body which, when acted on by alkalis, splits up into orcin and carbonic acid, and is the substance, or one of the substances, originally contained in the lichens which are employed for dyeing purposes. Since then a great number of similar substances, some well crystallised and all of them interesting, have been obtained from lichens. It is difficult to understand what function these well-defined chemical substances perform in the cells of such lowly organised plants as lichens. Whether so far as the plant is concerned they simply represent excrementitious matter is doubtful, but they certainly afford us a very beautiful though somewhat fugitive dye, orchil, and a pigment, litmus, much used by chemists as a reagent for acids and alkalis.

Another instance of a chromogen is seen in rubianic acid, a substance crystallising in yellow needles, obtained from the root of the madder plant, *Rubia tinctorum*. This root has been employed for ages in the East for dyeing turkey-red and other colours, but it was not until about the year 1835 that the substances to which it owes its tinctorial properties were detected.

Alizarin, the most important of these substances, was discovered and described by Robiquet. Specimens of this colouring matter in various states, and also of purpurin, another colouring matter contained in the root, and closely allied to alizarin, will be found in the showcase. Alizarin yields a variety of colours on calico—red, pink, black, lilac, etc.—according to the mordant used and the treatment employed. Now this substance, alizarin, is not contained as such in the plant—*i.e.*, it is not there in a free state, but exists in combination with glucose, forming a peculiar compound, rubianic acid, which is itself quite incapable of dyeing, and only exhibits tinctorial properties after decomposition with acids or ferments—*i.e.*, after it has split up into alizarin and glucose (grape sugar). It is the natural ferment of the root which in the ordinary process of dyeing with madder causes the decomposition of the glucoside (such is the name given by chemists to this class of substances) into alizarin and glucose. It should be stated that Rochleder was the first to discover a glucoside yielding alizarin by decomposition with acids. He called it ruberythric acid, but since this differs in some of its properties as well as in composition from rubianic acid the latter name is retained. The characteristic property of rubianic acid—that of yielding a potassium salt crystallising in plum-coloured needles (of which a specimen is exhibited)—is not mentioned by Rochleder. It was the analysis of this salt which led to the conclusion that alizarin contains 14 atoms of carbon, a fact of importance in connection with the artificial production of alizarin, which, if due attention had been given to it, would have shown that the attempts made to obtain the latter from naphthalene, a substance containing only ten atoms of carbon, could not possibly succeed. The other substances extracted from madder—rubian, rubiadin, purpuroxanthin, etc.—are mere chemical curiosities of no practical importance. The very beautiful substance, munjistin, obtained by the late Dr. Stenhouse from munjeet or Indian madder, should, however, not be overlooked. Purpuroxanthin, which is a product obtained by reduction from purpurin, is isomeric with alizarin, but does not dye mordants. Munjistin is purpuroxanthin carbonic acid, and rubiadin is probably methyl-purpuroxanthin.

The artificial production of alizarin from anthracene, a coal-tar constituent, is one of the most important discoveries of modern times, from a scientific as well as a practical point of view. The history of this discovery and its practical consequences will doubtless be discussed in connection with other exhibits, and may therefore be passed over here. It may, however, be mentioned that during the process of making artificial alizarin as originally carried out a considerable amount of another substance is formed, which was noticed first by Dr. Schunck, and named anthraflavic acid. This was shown by Dr. Perkin to be isomeric with alizarin, though quite incapable of combining with mordants. By fusion with caustic alkali, anthraflavic acid is converted into flavopurpurin, which is isomeric with ordinary purpurin, and is endowed with marked tinctorial properties. It is now prepared on a large scale for the use of dyers.

Chrysammic acid, the salts of which are coloured and remarkable for their golden, semi-metallic lustre, is also a derivative of anthracene. It was, however, obtained originally by the action of nitric acid on aloes. It belongs to the same class of compounds as picric acid, and, like the latter, may be employed for dyeing purposes.

Indigo, the well-known blue dye, is obtained, as most people are aware, from the leaves of various plants. In what state the colouring matter is contained in the indigo plant was formerly unknown, the leaves showing no blue tint when fresh and uninjured, but having the same green colour as any other leaves. Dr. Schunck showed that the colouring matter is contained in the plant as a pale yellow glucoside, easily soluble in water, which he called indican. This, like other glucosides, is decomposed by acids, splitting up into indigo and a peculiar kind of sugar, and thus the fact of indigo, which is an extremely insoluble body, being removed from plants by means of cold water was easily explained. There is a specimen of indican from *Indigofera tinctoria* among the exhibits, but, being a body very easily decomposed, it has already begun to show signs of change, the surface being covered with a blue film of indigo. Its physical properties are not interesting; it never assumes a crystalline form, always appearing as a yellow syrup. All commercial indigos contain a certain proportion of a red colouring matter. This red colouring matter was first obtained by Dr. Schunck in a state of purity, and called by him indirubin. It is a very interesting body, crystallising in red needles, subliming unchanged, and yielding solutions of a fine crimson colour. It has the same percentage composition as indigo blue, but is a more stable body. In dyeing it affords crimson in place of blue shades. Dr. Schunck has shown that by treating indican in a particular way before acting on it with acid it may be made to yield indirubin only, and as the latter would probably turn out a valuable dyestuff, on account of its great stability, a means is pointed out whereby the manufacturer would be enabled to produce a true red in place of a blue indigo.

As a curiosity interesting to physiologists as well as chemists, the specimen of indigo from urine may be pointed out. Dr. Schunck first showed that all urines, whether pathological or not, contain an indigo-producing body in minute quantities. The chemical nature of this body was first ascertained by Baumann, who showed that it was not a glucoside like the indican of plants, but the potassium salt of a peculiar acid, indoxyl-sulphonic acid.

The substances from cotton here exhibited are more interesting to the bleacher than to the dyer, since they represent together the matter which is removed from cotton fabrics during the bleaching process. Among them will be found a dark brown colouring matter which is the substance causing the brown tinge seen in raw cotton. All cotton, however white it may appear, contains some of this colouring matter, but the so-called Nankin cotton has more of it than other kinds. During the bleaching process it is partly removed by treatment with alkaline lye, and in part it is destroyed by the action of chloride of lime. The cotton wax may have something to do with the property that the cotton fibres possess of adhering to each other.

Dr. J. Peter Griess, F.R.S. (No. 7416).—In this exhibit we have specimens illustrative of the discovery of diazo and azo compounds, more especially the azo colours; also specimens of fabrics dyed with these beautiful and brilliant colours are shown. The history of the discovery of the first diazo compound, which was made in the year 1858, is thus related by Dr. Griess, in a letter to the writer:—"Dr. Gerland, when working in the laboratory of Professor Kolbe in Marburg, investigated the action of nitrous acid on amidobenzoic acid at the request of Kolbe. Thus the oxybenzoic acid was prepared, indicating a chemical change then considered of much importance. In like manner I investigated a means of converting picramic acid (amidodinitrophenylic acid), into the oxydinitrophenylic acid, $C_6H_2(NO_2)_2(OH)_2$, but I obtained instead of this latter a compound possessed of such striking and peculiar properties that I at once concluded it must belong to a completely new class of compounds. Analysis soon showed me that this peculiar compound had the composition $C_6H_2(NO)_2N_2O$. Naturally I soon submitted many other amido compounds in like manner to the action of nitrous acid, and obtained thus in almost every case the corresponding diazo compound. But the circumstance to which I was indebted for my success in obtaining the diazo compounds was that of the treatment of the amido compounds with nitrous acid in the cold, whereby the immediate conversion of the diazo compounds into other products was prevented, whereas in the earlier experiments of Hunt and Gerland a higher temperature was always attained, and consequently no diazo compounds could exist. Having obtained these diazo compounds, I then tried their action upon all possible substances, amongst which, of course, are the numerous class of amido compounds. I found that the diazo compounds combine directly with these, forming frequently brilliantly coloured substances which dye directly animal fibres. The first colouring matter thus prepared by me, which I obtained in the years 1861—62, was the benzene azo-α naphthylamine (see *Phil. Trans.* 1864, Part III. 679). It was first prepared on the large scale, to the best of my recollection, in the years 1865—6, by Caro, who was then chemist in the works of Messrs. Roberts, Dale & Co., of Manchester. I first recommended the oxyazobenzene obtained by me for use as a colouring matter in *Liebig's Ann.* 137 (1866)."

It will be observed from this, as in the case of Perkin's mauve, that these bodies were never thought of until they appeared, but came unexpectedly and unsought. At the present moment the conditions on which the formation of coal-tar colours depend are so well understood, that in forecasting a new substance it is not only possible to predict of what colour it will be, but also whether it will be a dye soluble or insoluble in water, etc.

The following azo dyes of principal historic interest are exhibited by Dr. Griess:—

1. *Benzene-azo-phenol.* Discovered 1861—63. See *Phil. Trans.* 1864, III. 689.
2. *Benzene-azo-α-naphthylamine.* Discovered 1861—63. *Phil. Trans.* 1864, III. 679.
3. *Diphenyl-disulpho-azo-α-naphthylamine sulphonic acid.* The first known cotton dye of the Congo red type. Discovered 1882. Eng. Pat. 1099, January 9, 1884.
4. *Dimethylaniline-azo-p-benzene sulphonic acid* ("Helianthine" or "Orange No. III."). Described *Ber.* **10**, 528.
5. *β-Naphthol-azo-p-phenol sulphonic acid.* First known red azo dye. Eng. Pat. 3698, October 4, 1877.

6. *Anisol-azo-β-naphthol sulphonic acid* ("Anisol red"). Eng. Pat. 4726, November 20, 1878.

The first diazo compound—viz., *diazodinitrophenol*, was discovered in 1858. (*Liebig's Ann.* 106, page 123.)

Dr. W. H. Perkin, F.R.S. (No. 741c).—This is an exhibit of very special interest, inasmuch as it marks a completely new era in the history of colouring matters and dyes. Perkin was the discoverer of the first coal-tar colour, but, singular to say, he did not in the experimental research he was carrying out expect a colour, and in fact, from the scientific standpoint, he did not want a colour. He was working in 1856 on aniline with a view to produce quinine, but obtained mauveine or "mauve" instead. Specimens of the original mauve are shown, both solid and in solution. The only small use to which mauve is now put in this country is for colouring postage stamps. It has been completely superseded by the finer methyl violets. Perkin patented his method for producing the colour, which was by oxidising sulphate of aniline, containing also sulphate of toluidine, with potassium bichromate, forming sulphate of mauveine or "mauve." A specimen of safranine is also shown, produced by the oxidation of the mauveïne.

In the year 1869, Graebe and Liebermann having shown that alizarin is an oxidised derivative of anthracene, Perkin devised a method of manufacture which was subsequently known as the English method, and by its use the necessity of first oxidising anthracene to anthraquinone was avoided. The anthracene was chlorinated, dichloranthracene being formed, which on treatment with fuming sulphuric acid, yielded the sulphonic acid of dichloranthracene. But on heating the mixture, hydrochloric acid and sulphurous acid were evolved, and a conversion into a sulphonic acid of anthraquinone took place.

The German method involved the direct oxidation of anthracene to anthraquinone by means of bichromate of potash and sulphuric acid, and the subsequent heating with strong sulphuric acid to ensure sulphonation. The sulphonated product is in both methods then fused with considerable excess of caustic soda, when the alkali abstracts the elements of the sulphuric acid and leaves a hydroxy product, which may be alizarin or one of its congeners. Specimens are shown of a wide series of anthracene, anthraquinone, and alizarin derivatives. Perkin also discovered a valuable means of purifying anthracene, by distilling it from potash. By this method, the Germans say, a 10 per cent. loss is sustained, but Perkin denies that such is the case. The residue is then found to contain a remarkable substance called carbazol, a body containing nitrogen; a specimen is shown of this beautiful body.

But alizarin is only one of a series of colours produced from anthracene, and the great advantage of the synthetical methods of preparing these colouring matters from the one common source, anthracene, is that according to desire, either one or other colour of this series may be obtained, whereas in working the madder root, the dyer must take and use what nature has put into his hands. Perkin also succeeded in preparing artificially for the first time the odoriferous principle contained in the sweet-scented Tonka bean—viz., *coumarin.*

Specimens of *cinnamic acid*, first prepared by Perkin, are also shown. Cinnamic acid is remarkable as being the raw material used in the preparation of artificial indigo.

Prof. C. Schorlemmer, F.R.S., and Messrs. R. S. Dale, B.A., and C. Schorlemmer (741a).—In the showcase in which Dr. Schunck's specimens are displayed will be found a small case of bottles and specimen tubes containing preparations neither large in bulk nor striking to the eye. Nevertheless, these specimens illustrate a very important series of chemical investigations. There are, firstly, a series of samples of the pure constituents of American petroleum, separated and prepared for the first time by Professor Schorlemmer. Schorlemmer conclusively proved that these constituents are not alcohol radicles, as was at first believed, but the hydrides of those radicles. The final result of this research was the grand division of organic substances into the paraffin series and the aromatic series. It has been stated that American petroleum contains absolutely none of the members of the benzene series, but this statement Schorlemmer shows not to be true, for amongst his little specimens may be seen some crystallised dinitrobenzene, which he prepared from Pennsylvanian petroleum.

Secondly, specimens of pure aurin and aurin derivatives, substances of considerable interest to the dyer, illustrating the joint researches of Dale and Schorlemmer, are also shown.

GROUP I.—CHEMICAL AND PHYSICAL APPARATUS.

W. H. Bailey & Co., Albion Works, Salford (No. 701).—This firm exhibits apparatus and machinery used chiefly by chemical manufacturers, bleachers, engineers, etc. Especially is the exhibit interesting for the variety of pyrometers shown, some of these, as well as other physical apparatus, being the inventions of Mr. W. H. Bailey. The question of the precise temperature at which a large number of chemical and physical changes occur, is one which has only recently received attention. The carrying out of operations on the large scale involving chemical changes is being brought into continually closer approach to scientific and laboratory method, and thus, just as the thermometer is essential in the latter, so the pyrometer must be adopted in the former. This firm exhibits Hargreaves and Robinson's hydrochloric acid pump, stopcocks for hydrochloric acid, and lead-lined valves for acids and sours. A pump for raising an almost equally corrosive liquid — viz., bleaching liquor, is also shown. Of patent pressure recorders, air compressers, pyrometers for all kinds of special purposes, such as for blast furnaces, japanners' stoves, portable army ovens, biscuit bakers, confectioners, for the Hargreaves and Robinson salt-cake plant (a model of which can be seen just opposite Messrs. Bailey's stand), etc., there is a great variety. The large automatic mortar and pestle exhibited is a curious as well as ingenious piece of mechanism.

Messrs. Doulton & Co., Deansgate, Manchester, and Lambeth Pottery, London.—This firm shows at Stand 702 interesting specimens of earthenware acid pipes, pumps, and taps of various sizes. Besides these, a feature is made of retorts, stills, receivers, condensing worms, store jars, chlorine retorts, unglazed chemical pipes for boiling in tar, specimen of hydrochloric acid pipes which have been in actual use, stoneware jars and bottles, with patent screw stoppers to 3in. diameter; 24in. diameter stoneware pipes, free from iron, for acid towers; plumbago and other crucibles, and various goods capable of resisting the action of fire.

Messrs. Follows & Bate, Limited, Gorton, Manchester (No. 703), exhibit apparatus used by wholesale drug and fine chemical manufacturers, as well as by viticulturists. A specimen of an edge runner mill, with granite rollers, measuring 18 by 6, and granite bed 2ft. in diameter; drug mills for grinding such friable materials as gentian, ginger, and copperas; also a powerful tincture press so designed that no part of the material operated upon can come into contact with iron or other metallic substance used in the construction of the press. The size of the hopper of this useful apparatus is nine gallons, and the calculated pressure of the plunger is six tons. A small iron circular tincture press, capacity one gallon, for chemists, a 65-gallon wine press and a grape crusher with rollers 29in. by 7in., numerous specimens of granite pestles and mortars, and an assortment of hand-power horizontal mixers for light powders, liquids, semi-liquids, and soluble compounds are also exhibited.

William Allen, Union Brass and Iron Works, Great Ancoats Street, Manchester (No. 717).—In this exhibit are shown Allen's improved filter-press in its complete form, and fitted up with 24 chambers; also a 3in. ram pump to be used with it. The press is suitable for the filtration of products in almost all kinds of chemical works. He also exhibits his patent regulus screw-down acid jug-valve, made of regulus metal, his plugs and seatings, cocks and injectors.

Messrs. Shaw & Connolly, electrical engineers, Manchester (No. 706), display Miles Settle's patent electric miners' lamps, as used at Darcy Lever Colliery, Bolton, and Madeley Colliery, Staffordshire: patent water cartridge, exploded by electricity, and all the necessary apparatus: mine signals, some fine specimens of the deep-seam cannel, a collection of cables and derivations for mine lighting, and a remarkable fossil tree (a Lepidodendron) from the Bolton coalfield.

Messrs. Shaw & Connolly, Varley Street, Manchester (No. 707), also exhibit insulated wires, as well as cables for submarine, torpedo, electric light, telephone, and telegraphic purposes. Five special varieties of insulated wires are shown, suited for different circumstances and purposes; also flexible cords, of which a large number of specimens are to be seen. There are wires differently insulated to suit all the following exigencies:—Great dryness, for internal work where walls are rather damp: decided dampness and exposed position (this variety the best to use in cotton mills, weaving sheds, and the like), when laid under water or subject to temporary permanent heat, also exposed to acid or other chemical fumes or to sea water. Besides these there is a variety like the last, but with additional coverings to protect and preserve from mechanical injury. This is the variety used by Holroyd Smith, and alone found available for the collectors of his electric tramways. A portion of such a collection is shown. Owing to the increase in size of dynamos, it was found necessary to provide a copper conductor of very large section for the connections, which at the same time was to be flexible enough to handle with the greatest ease. A piece of the largest cable ever made for this purpose is exhibited; it is used on an Edison-Hopkinson dynamo made for Germany, and is required to carry the current for 1400 lights. It is composed of 1813 copper wires, stranded in the best manner possible, and this has been done so successfully that, although the copper cable is $1\frac{1}{8}$in. in diameter, it can be easily tied into knots with the hand.

Specimens of cables used for telephone, electric light, torpedo, mine signalling, blasting, domestic, and other classes of work are exhibited. Cables for transmission of power are also coming into use, and as an example the cable is pointed to which is used by Messrs. Mather & Platt, and specially constructed by Messrs. Shaw & Connolly, to transmit the power to work their bleaching plant from the dynamo-house.

J. W. Lovibond, St. Ann's Street, Salisbury (No. 704), exhibits an apparatus for measuring colours called a tintometer. We believe this apparatus has a useful future before it. It is a new instrument, by means of which the depth of colour in liquids and solids can be accurately measured in degrees and placed in their position in a permanent colour scale, and mainly consists of a standard scale made of coloured glasses numbered according to their depth of colour, and an instrument for holding the glasses and the object to be measured. It is likely to be of service wherever colour is an index for manufacturers or where a permanent record of colours is desirable.

Edward Ward, F.R.M.S., 249, Oxford Street, Manchester, exhibits microscopes and appliances for microscopic investigation. Mounted slides and unmounted specimens, and photographic apparatus and lantern slides of scientific apparatus. An interesting feature of this exhibit is a special row of microscopes ready mounted and furnished with objects to be viewed at any time by those interested in Entomology and Natural History.

Joseph Davis & Co., Fitzroy Works, Kennington Park Road, London, S.E. (No. 705), exhibit Royal Polytechnic and other barometers, optical and scientific instruments of various kinds.

The Committee of Section III. and Watson Smith (No. 709).—Model of the Hargreaves salt cake plant, as used for the direct conversion at a high temperature (about 500° C.) of common salt into sulphate of soda, by means of sulphurous acid, steam, and air.

Harden Star and Sinclair Fire Appliance Company, Limited, Victoria Street, Manchester (No. 710).—All kinds of fire appliances. The Lucigen light apparatus, used during the dark evenings of last winter to enable the Exhibition workpeople to continue the erection of the buildings by night, is exhibited. It is a simple but very effective means of utilising the "creosote oil" of the tar distilleries, recently become so cheap as to be almost a waste product.

Joseph Casartelli, Market Street, Manchester (No. 712).—All kinds of surveying, mining, and engineering instruments, thermometers for industrial and other purposes, as well as hydrometers, etc., in which the special features of accuracy and lightness combined with strength are desired.

Franz Mueller, formerly Dr. H. Geissler, of Bonn, Germany (No. 713).—This exhibit contains, amongst other things, a complete Geissler's mercury air pump, with all the accessories, also sets of Crookes', Geissler's, and Puluj's tubes and apparatus. Attention must be especially called to the new form of the Crookes' apparatus containing rhombs of phosphorescent minerals, which on being electrified become apparently incandescent, and radiate the most beautiful coloured light. There is to be seen also a new electric radiometer, which carries phosphorescent wings. The fine show of delicate standard or normal thermometers will be interesting to the scientific chemist and chemical physicist. All the finer thermometers are constructed of Jena normal glass. The series of clinical thermometers contains instruments each of which is furnished with a kind of registering vernier with zero point graduation. A baro-thermometer is exhibited the thermometer of which is divided into $\frac{1}{100}$ths of a degree. This extremely sensitive instrument marks differences of height of only two metres ($6\frac{1}{2}$ to 7 feet). These are perhaps among the most striking objects in the valuable collection shown by the Geissler Institute. A beautiful illuminated display was made at this stand during the visit of the British Association.

F. C. Rein & Son, Strand, London (No. 715), show acoustic apparatus and instruments for deafness. **John Heywood**, Ridgefield, Manchester (No. 722), shows a completely fitted up chemical laboratory table, with all the newest appliances; whilst **Messrs. Mottershead & Co.** and **Messrs. James Woolley, Sons & Co.**, vie with each other in the beauty and interest of their exhibits of chemical and physical apparatus (Nos. 720 and 722a). The **Rex Bituminous Coal Company**, Hulme Hall Road, Manchester (No. 719), exhibit specimens showing the advances in the manufacture of patent fuel, a branch carried on to a wonderful degree of perfection in France and Germany, where coal is scarcer and dearer than in this country.

Henry Simon, Mount Street, Manchester (No. 718), exhibits models and drawings of apparatus by the use of which the smoke and fumes from coke-ovens of the beehive or open variety are completely abated, and in place of that smoke, tar and ammonia are obtained. The ammonia-water is worked up into sulphate of ammonia and liquor ammoniæ, whilst the tar is distilled and products obtained from which coal-tar colours are prepared. The colours thus made are exhibited, as well as fabrics dyed with them. There is shown a model of a Simon-Carvès recuperative coke oven, with adjustments for the recovery of by-products, and also a drawing giving a sectional elevation of the coke oven, with the apparatus for the automatic discharge of the finished coke.

There is also shown a model of a continuous ammonia still (Simon's patent), so arranged that either ammonia solution ("liquor ammoniæ") or sulphate of ammonia can be made at will, and that whilst the crude ammonia water is being fed in at one end, the liquors exhausted of ammonia down to some two-hundredths of a per cent. are running off at the other by a suitable overflow pipe. A drawing is shown of a sulphate of ammonia works arranged on Simon's principle at the Stafford Corporation Gasworks, and another of a liquor ammoniæ works as erected on the similar principle at the Michigan Ammonia Works, Michigan. Processes have, as is well known, been devised for extracting the benzene hydrocarbons from coal gas, so that they might be eventually worked up into aniline colours. We observe that a series of products similarly recovered from the gas of the Simon-Carvès coke ovens is exhibited. The gas was treated by the large Swiss colour manufacturing firm, Messrs. Durand & Huguenin, and an interesting series of aniline dyes thus obtained is shown, together with silks dyed with these colours.

The East Lancashire Chemical Company, Fairfield, near Manchester (No. 721), exhibits plant for bleaching cotton and linen yarn and cloth by the "blanchine" process—*i.e.*, using blanchine instead of soda ash, but no lime, and only very little bleaching powder and acid; a starch substitute for stiffening, and goods thus stiffened; also a patented substitute for bone size used for stiffening fustian goods. Of bone size it is alleged that it smells badly and communicates its odour to the goods; this substitute is guaranteed to do the work without communicating any odour. There is also a powder soap specially adapted for the "white grounds" of alizarin prints; it is commended by the firm on the score of economy and effectiveness. A variety of other drugs and chemicals used by calico printers and dyers, with models of apparatus, is exhibited at this stand.

George E. Davis, 301, Great Clowes Street (South West Gallery, No. 937), exhibits specimens of raw materials and products used and produced in apparatus and plant, the drawings of which are shown. The following is a list of the principal items in this collection:—

1. Drawings of the Poirion evaporator, with samples of esparto liquor and recovered ash.

2. Drawings of plant erected for making liquor ammonia direct from gas water.

3. The drawing of a pyrites smalls burner is shown. Seville smalls may be burnt in it with as much as 8 per cent. of Cu, so that half of this copper becomes soluble in acidulated water alone, and when the residue is calcined with salt, the spent ore or "blue billy" contains less than 0·15 per cent. Cu.

4. Specimens of benzene, toluene, xylene, solvent naphtha, naphthalene, anthracene, and sulphate of ammonia, made by Davis's patented carbonising process from the celebrated Rockingham coal.

5. Drawings of kilns for burning the spent oxide of gas-works. In these kilns every provision is made for the thorough combustion of the organic matter before coming in contact with the nitrous gases. If not burnt, the carbonic oxide or organic substances would reduce those nitrous gases and cause an undue consumption of nitre.

6. Drawing of a hydrochloric acid condensing tower of the usual pattern, except with regard to the method of taking off the acid, which is novel.

7. Glover tower on Davis's pattern having a low form, and only seven feet of packing, which in practice, it is claimed, has been found to answer very well. These towers are packed with a special blue brick, and the area of the tower is apportioned to the work to be done in it, the height always remaining the same.

8. A copper calciner, fitted with a Mond's smokeless fireplace.

9. Samples of products obtained on an industrial scale from the condensed gases from bee-hive coke ovens.

10. Samples showing the Davis and Aitken method of treating sewage and refuse water from various manufactories. Specimens are shown of the Salford sewage treated by this process, and the refuse water of a dyeworks before and after treatment.

GROUP II.—HYGIENE.

Messrs. Mottershead & Co. (No. 723), exhibit Benger's natural digestive ferments, peptonised foods, fluids and powders. The writer showed that beef tea prepared by adding a very little of the "Liquor" preparation to mince beef and water contains just three times as much nutritive matter as ordinary beef tea prepared from just the same proportions and quantities of mince beef and water without the addition of the "Pancreaticus Benger." A similar experiment, followed by the same success, was observed on adding some of the fluid to thick gruel or arrowroot, these compositions soon becoming liquefied through the partial conversion of starchy matter into glucose. These experiments were described by Sir William Roberts in the course of a lecture before the College of Physicians, London.

Messrs. James Woolley, Sons & Co., Market Street, Manchester (No. 725), exhibit antiseptic preparations, and all kinds of elegant and useful toilet articles, both perfumed and antiseptic.

Burroughs, Wellcome & Co., Snow Hill Buildings, London, E.C. (No. 724).—Professor Oscar Liebreich, of Berlin, first successfully investigated the chemical composition of the fat or grease of the wool of sheep, and found it to contain cholesterin. The commercial article is termed "lanolin," and it has a marvellous power of forming an emulsion on shaking up with water and of penetrating the skin when applied to it. This firm shows specimens of lanolin, lanolin pomades, soaps, cold creams, and ointments of various kinds.

M'Dougall Brothers, Port Street, Manchester (No. 726), exhibit a large variety of carbolic and sulphurous disinfectants in powders, liquids, and soaps: also Morris, Little & Son, of Doncaster (No. 727), show similar preparations, dog soaps containing phenols, etc.

Winser & Co., of Harter Street, Manchester (No. 728), lay stress on their new antiseptic and disinfectant which they term "salufer," chiefly composed of alkaline fluosilicates. It is stated that 1½ parts of this compound have greater power of preventing the growth of mildew on flour paste or cloth sized with flour or starch than 14 parts of the best chloride of zinc in the commercial form.

F. J. Harrison & Co., Limited, of Leicester (No. 729), and Swan & Leach, of Albert Square, Manchester (No. 730), show many varieties of sanitary and disinfecting soaps, soap powders, and preparations for household, toilet, and other uses.

GROUP III.—DESTRUCTIVE DISTILLATION.

The Broxburn Oil Company, Limited, Royal Exchange Square, Glasgow (No. 750).—This firm exhibits specimens of the products obtained by the destructive distillation of Scottish boghead shale, together with samples of the raw material itself. It is an industry originally founded by the late Dr. James Young, F.R.S., about thirty years ago. Dr. Young commenced, however, not with boghead shale, but with the boghead cannel itself, a mineral the identity of which with cannel coal was disputed in a celebrated lawsuit started to upset Young's claims. This suit failed in its object, and so vigorously was the manufacture of paraffin oils, naphthas, and wax pushed that the mineral became speedily exhausted. A fine specimen of this now extinct Scotch mineral, presented to the writer by the late Dr. James Young, is to be seen at Stand 781. In the great lawsuit already referred to the presence of a single characteristic coal fossil in the mineral would have quickly decided the case and have saved much expenditure of money, but no fossils were to be found in this boghead cannel. It is interesting, however, to mention that Professor W. Boyd Dawkins, when recently in Australia, identified a cannel which is practically identical with the old Scottish boghead, and fine specimens were brought over by him, and are now to be seen in the Geological Museum of the Owens College. The interesting point is that the Australian boghead *does* contain fossil remains. The first record we have of the manufacture of paraffin wax is that by a Manchester man (nevertheless a Scotchman), Mr. John Thom, of Birkacre (and of the firm of M'Naughton & Thom), who made it before the year 1835 by Reichenbach's process from the products of the distillation of wood, as he informed the writer. He has still a specimen of the paraffin wax then actually put in the market. Mr. Thom was then the chemist in a works at Camlachie, near Glasgow. The present approximate annual production and value in the United Kingdom of the staple articles manufactured by the paraffin oil trade represented over £2,250,000. In the year 1886, to produce this value in the staple articles, there were consumed 1,816,600 tons of shale, and in the manufacturing processes there would be over 500,000 tons of coal consumed. The capital invested in the paraffin oil trade amounts to about £2,000,000. The articles exhibited by the Broxburn Company are (1) crude oil; (2) sulphate of ammonia; (3) the refined products of the crude oil, which are burning oil in several qualities, naphtha of shale spirit, lubricating oil in various qualities, ordinary and debloomed; solid paraffin scale, the same in a refined state as wax of various qualities and candles prepared from it. The specimens of candles vary from the cheapest to the finest hand-painted kinds for drawing-room use.

The Linlithgow Oil Company, Limited, Edinburgh, and 4, St. Ann's Square, Manchester (No. 748).—This is also one of the Scottish shale distilling firms, and exhibits fine specimens of its raw and manufactured products, similar to those of the Broxburn Company.

The Dee Oil Company, 5, Cross Street, Manchester, and Saltney, Chester.—We now pass on to a handsome exhibit, illustrating the extraction of paraffin wax and paraffin products, not by destructive distillation from shale or cannel, but by direct distillation from crude American petroleum residues first deprived of their light naphthas in the States before export to this country. This is a special line of paraffin industry of itself, and the annual production and value in this country of the staple articles thus produced amount to about £150,000. For this an annual consumption of raw materials takes place represented by about £50,000. The works of this firm are established just on the borders of Cheshire and Flintshire, at Saltney, near Chester, and the history of the oil trade in the locality of North Wales is one of peculiar interest. The trade may be said to have had its origin in the discovery of "curley cannel" coal in Flintshire, on the borders of Cheshire, about 26 years ago. This discovery led to the establishment of many companies and works in Flintshire for the production of paraffin oil, and the new industry was commenced with great vigour. However, American petroleum also came to the front, and the competition became too severe for the Flintshire paraffin industry. Burning oil reaches this country from the United States far cheaper than it could be made here from English products. At the present moment there is not a single firm in North Wales producing oils from the curley cannel of the district, which, moreover, is nearly exhausted. During the decadence in this locality of the cannel-paraffin industry, one of the last of the surviving companies—viz., the Coppa Oil Company, who amalgamated with the Dee Mineral Oil Company, which then assumed the title of the Dee Oil Company, under which title it trades at the present time. There is a lesson for chemical manufacturers in this little history, one which as to facts has been repeated and will be repeated scores of times. It is this:—In times of change, depression, and revolution of circumstances only those can survive and continue to flourish who possess elasticity and energetic mental and physical vigour, backed up by and supported with scientific knowledge and intelligent observation. It is clear that the Dee Oil Company possessed these qualities, and the subsequent history of the firm shows that they were thoroughly needed. Thus, somewhat later, it was found that the paraffin scale and crude wax market became glutted, and no competition could be longer undertaken in that direction. The Dee Company therefore utilised the apparently hard circumstances by at once erecting its own candle works, where it could manufacture its own raw material into candles and so remove it beyond the region of impracticability and danger. To cut down other expenses the company further erected its own sulphuric acid works, and will shortly put up its own stearin plant. Competition was thus fought with its own weapons. The samples of manufacture exhibited comprise specimens of crude petroleum as taken from the American wells, refined petroleum, burning oils and residuum, which, as has been stated, is the material used by this firm. From it are manufactured lubricating oils of different brands, cylinder oils, and a special class of oils termed "valvolines" sterling. They are oils for internal lubrication, and are said to be superior to even the best makes of cylinder oils. They are especially recommended for use with sight-feed lubricators and in all high-pressure steam cylinders. They are remarkable for a high flash point (510° to 550° F.) a low setting point (under 32° F.), and a great viscosity even when exposed to high temperatures. An entirely new method is used for their preparation, avoiding, it is said, distillation and treatment with acids and alkalis. Three grades are exhibited—"torpedo oil," for use on torpedo boats, launches, etc.; "dynamo oil," adapted for electric machines; "gas engine" and "ring spindle" oils. We observe also a preparation for therapeutic use, *oleum Declina*, a medicinal oil for skin diseases. Besides these we see many other varieties of oils, and also fine specimens of paraffin wax, and candles, both plain white and coloured.

Messrs. Ragosine & Co., 7, Idol Lane, Great Tower Street, London, E.C. (No. 733).—This exhibit is one illustrative of the advanced present position of the Russian petroleum industry. Two of the most wonderful things in connection with this industry are its apparently inexhaustible stores of natural raw material in the neighbourhood of Baku, South Russia, and the enormous rapidity with which that industry has developed. To give an idea of this advance and development, it may be interesting to sketch the history of the firm whose beautiful exhibit is under consideration — that of Ragosine & Co. In 1876, when the monopoly in petroleum at Baku was abolished by the Russian Government, the production began at once to increase enormously, but so far the only valuable products obtained from the crude oil were spirit and burning oil. Since the Russian crude oil only yields 27 to 30 per cent. of these, there remained an enormous production of residuum, which was for a long time used as fuel or entirely wasted. It was Victor Ivanovitch Ragosine who first suggested the utilisation of the heavier portions of the crude oil for the manufacture of machinery oils and greases. The firm of V. I. Ragosine & Co. was founded by him in 1876, at Nijni Novgorod, with a capital of 200,000 roubles. A refinery was built at Balachna, on the Volga, in 1876, and a second at Constantinow in 1880. The capital of the Company was raised by successive fresh issues to 3½ million roubles, and in 1880 this Company obtained an imperial charter. The works at Balachna and Constantinow are supplied with raw material from Baku, by a system of tank barges, which are towed up the river during the month of May. The two refineries together have storage in iron tanks (each of about 2500 tons capacity) of upwards of 30,000 tons of crude oil and residuum. The plant at the two works includes 54 stills, and is capable of treating 35,000 to 40,000 tons of crude oil per annum, and of producing from 30,000 to 35,000 tons of lubricating oil, etc. The oils made from the Russian petroleum were first introduced into England in 1878. No mineral oils of the same "body," it is said, have been seen before, and this "body," or better, "viscosity," of the Russian mineral lubricating oils indicates their special advantage. The viscosity of Russian oil of specific gravity 0·915 is about six times that of American oil of the same specific gravity at 60° F. The viscosity diminishes rapidly as the temperature rises, but even at 120° F. the Russian oil is claimed to possess three times that of the American of the same specific gravity. As compared with colza and olive oils, the Russian of 0·905 specific gravity has roughly about two or three times the viscosity at 60°; at 120° F. they are about equal. These statements are confirmed by the tables of William McIvor and Boverton Redwood. Hence (1) high viscosity—*i.e.*, lubricating power; (2) freedom from acid; (3) absolute immunity from "gumming," since oxidation and drying cannot take place; (4) very low freezing point. The Russian crude oil contains practically no paraffin. A valuable product, viz., paraffin wax, is lost by this peculiarity, but the cost of freezing out the scale from the lubricating oil is saved. The burning oils, "petroleum" of specific gravity 0·826, No. 3, now largely used in this country and said to have a higher flash point than the corresponding American product, and equal illumination, "pyronaphtha" and "Australine," special oils of very high flash points—viz., 200° and 130°, and used in specially-constructed lamps, are pressing the American oils very hard. When the inert residuum of the American petroleum is destructively treated in red hot tubes, a large amount of charring takes place, and very little—scarcely any—increase of value in the distillate occurs; but if Russian petroleum residues are similarly treated, as was first discovered by Letny, and Liebermann and Burg of Berlin, these residues are converted, it is true with much charring, into the true coal-tar products, benzene, toluene, napthalene, anthracene, etc. Besides a fine collection of crude pretroleum, with naphthas, lubricating and burning oils of all kinds, as well as oils for other special uses, a set of interesting specimens of aromatic hydrocarbons, such as are obtained from gas tar by the tar distiller, and used in the making of aniline and other coal-tar dyes, is exhibited. Those specially interested on proceeding to Stand No. 781, may see there a specimen of crude anthracene obtained from the Russian petroleum in the way specified, and another of 20 per cent. alizarin prepared from the anthracene, and finally a piece of printed and dyed cotton in the colouring of which some of this alizarin was used. It has been, however, sufficiently proved by numerous practical experiments that the method of preparing coal-tar hydrocarbons by carbonising the petroleum or residuum will not pay, and we believe the process is now entirely or almost entirely abandoned.

J. C. & J. Field, Upper Lambeth Marsh, London (No. 752).—This firm, though also manufacturing and exhibiting a special kind of soap, is best known for its "ozokerite" candles, ozokerite being a peculiar mineral wax occurring largely in Galicia, and containing a very considerable proportion of paraffin. It is thus a kindred substance with crude pertroleum. Ozokerite was probably formed by the denuding action of water on peaty and similar vegetable remains, the vegetable part being gradually removed and the insoluble resins washed away or deposited. Till about 1770 wax and tallow were the sole ingredients of candles. The wax candles were "rolled," the tallow "dipped" or "moulded." The wicks in all cases were of twisted cotton, except in the cheaper tallow candles, in which rushes, partly stripped, were used. In 1850, James Young having isolated paraffin, J. K. Field took out a patent for manufacturing candles therefrom, which at once became very popular. Subsequently various members of the Field firm patented different forms of the candle—spiral, cable, etc.,—to which the plastic and transparent paraffin readily lent itself. In 1872 the attention of F. Field, F.R.S., was drawn to the mineral wax ozokerite, long known in Galicia. In 1874 a patent was taken out for the distillation of the crude earth wax, and the white, very hard paraffin now known as ozokerite was produced (melting point 142° F.). The recent introduction of semi-refined paraffin scale into the candle trade has almost annihilated the composite and tallow candle branch of the industry. The amount of candles and night-lights produced in Great Britain annually cannot be much under 30,000 tons: probably it exceeds this estimate. Price's Company turn out over 60,000,000 night-lights annually. The amount of palm oil imported into England exceeds 40,000 tons; tallow (exclusive of home consumption), 20,000 tons. (See Field's Cantor Lectures, *Journ. Soc. Arts*, 1884, and Rep. on Oils and Fats, C.I.E., 1886.) The principal part of Messrs Field's exhibit, the "samphire soap," is an article made by Dr. Alder Wright's ammonia process, and in this process all free alkali is removed. Moreover, a small quantity of free iodine is introduced, and glycerine of specific gravity 1·26 is substituted for the 20 per cent. of water usually present in toilet soaps. Eucalyptol, the essence of the *Eucalyptus globulus* in an iodised and semi-saponified form, is finally added.

PRICE'S PATENT CANDLE COMPANY, LIMITED, Belmont Works, Battersea, London, S.W.—This exhibit is one made by a firm which has a remarkable history. It is owing to a discovery made by a member of this firm that cheap and pure glycerine may now be had in abundance. To describe the development of the firm in detail would be out of the question, for, to begin with, more than 80 patents have been held by Price's Company. The great French chemist Chevreul, now over 100 years of age, but still active as a chemist, in 1811 began his researches on the constitution of fats and oils, and in 1823 he completely published his discoveries in this direction. In conjunction with Gay Lussac he attempted the industrial application of the scientific principles he had made known, but did not attain the success he doubtless anticipated. It was reserved to M. de Milly to lay the foundation of the stearic candle manufacture in 1832. In 1833 the "Bougies de l'Etoile," as the candles of MM. de Milly and Motard were called, were sold in Paris at about 1s. 8½d. per pound (retail), and at this price were placed on the market to the extent of about 25 tons per annum. In 1829 Mr. James Soames, of London, separated cocoanut oil into its solid and liquid components by pressure. He took out a patent for it. The patent was purchased by Mr. William Wilson and his partner, who worked under the title of "E. Price & Co." They perfected it, and produced by its aid cocoanut candles and lamp oil. In 1847 the concern passed into the hands of "Price's Patent Candle Company," Mr. William Wilson becoming the first chairman, and his two sons—J. P. Wilson and G. F. Wilson—the managing directors. The plaited wick, patented in France in 1825 by Cambacéres, was introduced into England by Henri Meyer, subsequently manufactured near Derby by Mr. Thomas Topham, and he in 1836 was supplying the wick to E. Price & Co. In the year 1840 Mr. J. P. Wilson, whilst endeavouring to produce a cheap self-snuffing candle for the coming illumination in honour of the marriage of Her Majesty Queen Victoria then approaching, succeeded in making such candles of a mixture of equal parts of stearic acid and cocoanut stearin. They gave a brilliant light, required no snuffing, and could be sold retail at 1s. per lb. The new candles came rapidly into notice, and the sales advanced in a manner entirely without precedent. They were termed "composite," because of the mixture of materials in them. Such was a new and successful departure in illumination for our homes and on festive occasions at the date of the marriage of Queen Victoria.

In 1840 George Gwynne took out a patent for the distillation of the fatty acids in vacuo. It is these fat acids which, chemically united with glycerine, form true fats, much as sulphuric acid united with soda forms a salt, sulphate of soda. The knowledge which had already been acquired that these fat acids could be distilled without destruction or decomposition was thus for the first time commercially applied. But in 1842—43 Messrs. Price & Co., in the names of W. C. Jones and G. F. Wilson, patented a still more important discovery, superseding the first. They discovered that all the good effects of the vacuum process could be gained by substituting the use of free steam. Thus the costly vacuum still was avoided. With respect to the hardening of fats, Fremy, another great French chemist, had shown in 1836 that treatment with 50 per cent. of their weight of sulphuric acid in the cold was needful. In commerce this was impracticable. Clarke and Gwynne patented a process based on the foregoing in 1840, but Jones and Wilson subsequently proved that if the mixture were warmed, not cooled, then 33 per cent. of sulphuric acid would suffice and still all the good results be obtained that were realised in the other process. Another commercial success was the result. In 1848 the night-light patent of G. M. Clarke, and in 1849 the night-light business of S. Childs were acquired, a new factory was erected, and in 1852 the sale of night-lights already amounted to over 12 millions per annum. Some years before the English millowners could be induced to use oleic acid instead of olive and other oils for the oiling of wool, that acid, as produced in large quantity in the manufacture of stearic or hard candles, had been thus successfully used on the Continent. The process of Messrs. Price & Co. by distillation appeared likely to remove the impediment in this country, and so in 1851 the English patent of Messrs. Alcan and Peligot (another noted French chemist) was secured for the use of oleic acid as a "cloth oil." However, it was only after some time the prejudice of the Yorkshire millowners was overcome. In 1854 R. A. Tilghman took out his English patent for acidifying fats and separating them into fat acids and glycerin by means of contact with water under high temperatures and pressures. The Company took an exclusive licence under this patent. However, a still further and very material advance was made when Messrs. G. F. Wilson and G. Payne, in 1855, discovered that neutral fats could be broken up (a kind of partially destructive distillation or, better, analytic distillation or hydrolysis) by distillation with superheated steam alone. Before the close of this same year Mr. G. F. Wilson secured another discovery and patent for his firm of great commercial importance and scientific interest. He found, namely, that glycerin could be distilled without decomposition by the use of steam. Previous to this date a chemically pure glycerin had never been seen. Under the new patent such a product became not only possible but commercially so. In 1850 James Young obtained his celebrated patent for the production of paraffin hydrocarbons by the destructive distillation of coal at a low red heat. In 1853, seeing the progress of Mr. Young's paraffin industry, Mr. Warren de la Rue took out patents for working the Burmese or Rangoon petroleum. Hardly had the first exports of some 10,600 gallons of burning oil prepared from this Rangoon petroleum to New York in 1859 been effected when "oil was struck" in America, and this new discovery of petroleum upset all calculations as to the value of the Rangoon article. Meanwhile Messrs. Price & Co. turned their attention to the perfection of the candle and other machinery. The increased use of American burning oil had no slight effect on the Company's sales, for whereas in the five years 1857 to 1861 46,905 tons were got rid of, in 1862 to 1866 only sales of 43,609 tons were effected. The firm now carried the war into the enemy's camp, and from using paraffin scale from Scotland and the United States a forward movement was made, first in the patenting a new process for producing fine white paraffin wax without the use of the dangerous spirit generally used in the washing processes, and secondly, in enlarging and improving its paraffin refinery at Battersea. At the present time, it is said, Price's Company is the largest refiner of paraffin in the world. By this indomitable perseverance and intelligent co-operation with circumstances the falling off already referred to in the transition period was soon recovered, the previous highest sales surpassed, and in the five years 1882 to 1886 the saleable produce rose to 80,205 tons. At present the approximate annual production of the articles manufactured by Price & Co. is 18,000 tons: value about £700,000. The annual consumption of raw materials is about 19,000 tons. The present annual production of paraffin candles in this country is 27,000 tons; of stearin candles 7500 tons.

After what has been recorded of the invention of a new and brilliantly burning candle, just in time for household use and for purposes of festive illumination about the period of Her Majesty's marriage, it would seem natural that some special memento might be afforded of such an occasion in the Exhibition: this has been the case, for Messrs. Price exhibit a life-size bust of Her Majesty in pure white stearic acid, standing on a pedestal of the same fat acid, supported on a cube of the material used in the manufacture of the gold medal palmitin candles. The soaps exhibited by this firm are extremely varied, and are of excellent quality. An interesting exhibit of candles, night lights, tapers, etc., and the machinery used in forming them is to be seen in the Machinery Annexe, Stand No. 416.

I. Levinstein & Co., Manchester (No. 742).—There is here a model of its kind, for it is both eminently beautiful as well as instructive. Very artistic, too, is the arrangement of the little pavilion, which forms the show-stand, for if the visitor go inside it he at once loses sight of any specimen of dye, colour, or other material used in the preparation and colouring of the exquisite ornamental silks, wools, and flowers, which are so arranged as to make the interior resemble that of a conservatory. Let him proceed to the outside, and immediately on passing the doorway he at once loses sight of the ornamental and artistic embellishments, and a series of elegantly arranged chemical specimens presents itself. He may now see and examine all the materials and products through every stage, from the raw coal to the finished dye and colouring matter, as well as other useful coal-tar products. But Mr. Levinstein has so devised it that not only are the specimens and samples shown, but they are exhibited in the proportions in which they are practically obtained in the factories, so that, commencing with the cubical block of coal weighing 1 cwt., the specimens shown in the lower compartments of the pavilion represent also the proportions by weight obtainable from the 1cwt. of coal aforesaid. We observe on the 1cwt. block of coal a small bottle containing saccharine from coal tar, the announcement of the manufacture for the first time of which was made by Mr. Levinstein nearly two years ago. The little sample in question represents the actual proportion obtainable from the large block of coal on which it rests. Besides the raw and intermediate products, which are shown in all completeness of detail, about 100 different coal-tar dyes are also exhibited. As regards illustrations of dyeing power as exhibited in the superficies of fabric which can be dyed to a full shade, the 1cwt. of coal already mentioned is here again brought usefully into requisition, and around the block are arranged some folds of flannel dyed scarlet, and representing accurately, therefore, the amount of scarlet-dyeing power (if it may be so described) that resides in the 1cwt. of coal. Especially we notice fine specimens of the eosines, naphthol yellow and azo-scarlets for which this firm has obtained such celebrity.

Messrs. Josiah Hardman & Co., Miles Platting, Manchester (No. 747).—An accurate and beautifully constructed model of the tar distillery in its most complete form first strikes the eye of the visitor. This model is moreover no fanciful representation, and to show how thoroughly its arrangement and planning have been thought out and designed, it is modelled to scale, and on its premises are arranged sulphuric acid chambers, with all the paraphernalia of a vitriol works, so necessary an adjunct in these days of low prices, when materials must be as far as possible manufactured direct rather than bought. As regards the splendid collection of specimens, these are arranged so as to exhibit not only quality but also proportion by weight derived from a given unit weight of raw coal. A large cubical block of coal is shown and the weights of useful products derived also, and, further, the quantities of different fabrics that can be dyed with the given proportions of colours that may be extracted from the block are exhibited. This furnishes an interesting and striking idea of measurement of the colouring capacity that is latent in ordinary gas coal. The exhibit of course includes crude as well as purified products obtained from coal tar, ammoniacal liquor and spent oxide.

Messrs. Hardman & Holdens, Miles Platting, Manchester (No. 746).—A kind of branch firm of the foregoing. Here is seen a most attractive and interesting exhibit arranged to illustrate the manufacture of alizarin from coal tar, and showing a series of chemical products with their derivatives, remarkable for their purity and beauty. The practical application of alizarin to cotton is shown by a variety of dyed and printed yarn, cloth, velvet, etc. Alizarin colours on fabrics are also shown alone as well as in conjunction with other dyes. Special prominence is given to the exhibition of specimens illustrating the advances made in the dyeing of silk and wool with alizarin. Skeins of silk in six colours, showing four shades of each, also examples of dyed and printed silks, form a new and pleasing feature in the exhibit. Moreover, samples of wool in various shades, also cloths and tweeds in which alizarin-dyed wool predominates, are shown. The old original madder in various forms is not forgotten, and some specimens of madder-dyed and printed fabrics are exhibited, among the most interesting being the Indian dresses, woven and dyed with munjeet (*Rubia munjista*) by the natives.

It was not until the expiration of the German patents that Hardman & Holdens, who were first in the field, were able to start their alizarin work. There are now three English makers, and it seems probable that ere long England will make all the alizarin she consumes. One effect of this competition following the expiration of the patents has been that whereas four years ago the price of alizarin was 2s. 6d. per lb., the present market price is only 8½d. per lb.

Messrs. Sadler & Co., Limited, Cleveland Chemical Works, Middlesbrough (No. 744).—This firm makes a specially interesting exhibit of coal-tar products, crude and refined, and amongst the latter notably alizarin, aniline, and other coal-tar dyes; likewise acids, alkalis, and other chemicals are represented as being manufactured for use or in order to the working up of by-products. It is worthy of mention that Messrs. Sadler & Co. were the first manufacturing chemists to recognise the practical value of the coal-tar from the coke ovens on the Simon-Carvés system as worked by Messrs. Pease & Partners, at Crook, near Darlington, and long before other manufacturers were willing to admit the genuine character of that tar and ammoniacal water, or thought anything about the subject, this firm had made contracts for both products and worked them to profit: and hence Messrs. Sadler & Co. were certainly the first firm, at all events in this country, to make alizarin and other coal-tar colouring matters from coke-oven tar. As a record of enterprise, the foregoing may be placed at the head of the brief list now to follow. Alizarin is one of the specialities of this firm, and in its manufacture Messrs. Sadler enjoy the advantage not only of making the raw material, anthracene, direct from coal tar, but they make at the same time all the other chemicals which are necessary for its complete production. By their process they produce an article of exceptional purity. The beautiful dyed and printed specimens illustrating the effect of Messrs. Sadler & Co.'s alizarin and allied colours on the fibre were furnished, we understand, by Messrs. E Potter & Co., of Dinting Vale. With regard to aniline colours. Messrs. Sadler & Co. commence with the tar, distil it, and proceed onwards to the finished colours. Their magenta is produced by the nitrobenzene process. Another dyestuff—viz., Bismarck brown, is made by a patent process direct from dinitrobenzene, the benzene for this being extracted from coal gas.

This firm manufactures oxalic acid largely from sawdust. Amongst the alkali products, soda is made from salt, which occurs largely in the strata below the ground on which the factory stands, and the sulphuric acid from pyrites obtained from the Cleveland hills in the neighbourhood. Fuming sulphuric acid, considerably used by the dye manufacturer, Messrs. Sadler make from bisulphate of soda.

Epsom salts, for a great number of years made in Middlesbrough from the magnesian limestone, are now entirely manufactured from kieserite, a refuse product of the Stassfurth mines.

All the waste products of the factory which possess any value for the purpose are mixed with dissolved bones and superphosphate, which is also made in large quantities and sold in the form of manures.

The British Alizarin Company, Limited, Silvertown, London, E. (No. 736).—This beautiful exhibit, mainly a reproduction of the one which excited so much admiration in the late International Inventions Exhibition, and which gained a gold medal there, is not only of present interest, but it illustrates well the history of the development of the madder and alizarin industries.

1st. Is a series of specimens illustrating the growth and form of the madder plant and various dyeing products derived from it. These natural dyes have been superseded by the "alizarins." Specimens are also shown of cotton prints prepared with madder colours.

2nd. There are specimens showing the crude products from the distillation of coal-tar.

3rd. Specimens illustrating the process of the manufacture of alizarin, flavopurpurin, and anthrapurpurin from crude anthracene, together with others exhibiting some of the chemical properties of anthracene and its derivatives, as well as further specimens of the pure chemical substances which occur along with pure anthracene in crude coal-tar anthracene.

4th. Numerous specimens of printed and dyed cottons, muslins, velvets, cretonnes, etc.; also others of dyed turkey-red cloths and yarns produced with the alizarin colours of the British Alizarin Company, Limited. Some of these specimens show the alizarin in conjunction with other colouring matters.

5th. According to an instructive system of arrangement, a series of samples illustrating the various stages of cotton printing and dyeing with alizarin is shown—*e.g.*, cotton cloth in all the following conditions and in the following order:—Grey, bleached, mordanted, fixed, dyed, oiled, steamed, cleared and finally finished.

6th. Specimens exhibiting the shades obtained by the same mordant from alizarin, anthrapurpurin, and flavopurpurin respectively.

7th. A "five-striped swatch" (mordanted and dyed cotton cloth), showing the colours produced by various mordants from the same alizarin dye-bath. Besides the foregoing are two Indian figures, draped in native costume, printed with alizarin, and numerous samples of wool and silk dyed with the same colouring matter.

Messrs. Brooke, Simpson & Spiller, Limited, Hackney Wick, London, E.; also 106, Portland Street, Manchester (No. 732).—This firm is one which has a history, for in earlier days, under the style of Simpson, Maule, & Nicholson, it acquired a European reputation for violet and blue dyestuffs. The magentas and acid magentas produced by Messrs. Brooke, Simpson & Spiller have a reputation for exceeding purity and beauty of colour. Dyed and printed patterns indicate the applications of the dyestuffs exhibited.

Society of Chemical Industry of Basle, Switzerland, formerly Messrs. Bindschedler & Busch (No. 743).—W. G. Thompson & Co., Cooper Street; and O. Isler & Co., Marsden Street, Manchester.—The writer has had the privilege of inspecting the works, laboratories, and offices of this, the foremost of Swiss colour and dye manufactories, comprising aniline and azo colour factories, and also an extensive alizarin works. The laboratories are extensive, excellently arranged, and form a leading feature of the establishment; they are manned by a staff of 15 chemists. Throughout the works, cleanliness and good order are qualities which at once strike the visitor; excellent discipline is also everywhere observable. There are from 350 to 400 workmen and foremen. To give an idea of the steam power required in a factory of this kind we may mention that 11 steam boilers, representing in the aggregate 1100 horse-power, are regularly at work. No less than 22 steam engines are in operation for the communication of power. The specialities quoted by this firm from a long and well-classified list of their products are the following:—Violet 5 B crystals, ethyl purple, Victoria blue B and 4 R, night blue, auramine, tartrazine, acid magenta, fast green 3 B, crystals acid violet 7 B, alkali violet.

St. Denis Dyestuff and Chemical Company, Limited (Poirrier & Co.), St. Denis, Paris, and 3, Booth Street, Manchester (No. 740).—This exhibit is well worthy of the foremost firm in France in the manufacture of dyestuffs. Amongst the colouring matters shown, we observe some interesting ones of the azo class, and not the least so that one termed "roccelline."

Manchester Aniline Company (Charles Truby & Co.), 55, High Street, Manchester, and Clifton Junction (No. 738).—This exhibit comprises specimens of aniline oil for dyeing, calico printing, and colour making, of essence of mirbane (nitro-benzene) for scenting soap, dinitrobenzene and toluene, pure naphthalene, nitronaphthalene, arseniates of soda, oleine as alizarin oil, soluble oil, and all the special materials for sizers and finishers.

Von Hohenhausen & Co., Yew Tree Chemical Works, 303, Collyhurst Road, Manchester (No. 745).—An elegant display of all the materials used by the calico printer and dyer which come under the headings of mordants, dung substitutes, preparing liquors, assistants, etc., together with some special dye-stuffs. The sulphocyanides and acetate of chrome deserve special mention.

Dan Dawson Brothers, Milne Bridge Chemical Works, Huddersfield (No. 737), exhibit a neatly-arranged series of specimens illustrating the chemicals and coal-tar dyes manufactured by them.

Charles Lowe & Co., Reddish, near Stockport, and Piccadilly, Manchester (No. 739).—With the name of Charles Lowe that of chemically pure carbolic acid is intimately associated. Mr. Lowe was the discoverer of a finely crystalline hydrate of carbolic acid, and the name of his firm has for long been taken as a guarantee of excellence and purity of manufacture of the carbolic acid preparations and derivatives — some of them dyestuffs — which are manufactured there. A novel method of exhibiting the phenol- and other colours in a kind of glass case is adopted.

J. C. Siegerist, 41, Faulkner Street, Manchester (No. 731), representative of the Fabriques des Produits Chimiques de Thann et de Mulhouse, Alsace.—In the first place are exhibited colours in dry, paste, and liquid states, specially prepared for calico printing. These colours are, almost without exception, "finished colours"; that is to say, specially prepared colours, which, in order to be printed upon the cloth, simply require mixing with a thickening such as starch, gums, albumen, etc., according to the nature of the colour. No mordants having to be added to these colours by the printers, the latter are easier for them to manipulate, and are said to give more satisfactory results as to uniformity of shade, etc., than colours made up by themselves. There are colours for ordinary calico printing, indigo discharge, and others for printing on alizarin red-dyed cloth. The principal feature in the latter (both blues) is that they are simply printed on the cloth with a thickening, steamed, and then washed. This gives a very good imitation of indigo discharge on turkey-red. There is also one colour (Alsace green) for piece dyeing, and this colour can be discharged. With the exception of a few, these colours are said to be fast to light and soap. We observe (2) colours for printed wall papers; (3) colours for wool dyeing. Amongst these is an aniline blue which gives shades equal to indigo. The colour is even faster than indigo both to light and soap, and no acid can discharge it. It stands milling and felting perfectly well. (4) Chemicals used as mordants, etc.; (5) substances used in the making of aniline colours; (6) chemicals for producing blacks on cotton goods; (7) aniline colours for wool, silk, and cotton; (8) glycerines made from pure stearin; (9) albumens; (10) Senegal gums.

B. Kuhn, agent for **L. Durand and Huguenin**, Basle, Switzerland, 55, Bloom Street, Manchester, and 36, St. Mary-at-Hill, London, E.C.—An interesting display of coal-tar colours is shown for dyeing and printing wool, cotton, silk, etc., with patterns to illustrate the shades and character of these colours. Special dyes for leather are also exhibited, with specimens of that material dyed and printed. An interesting feature of the exhibit is, however, the new coal-tar medicaments shown. First we observe "*salol*," or phenyl salicylate, which has been recently applied with success as an anti-rheumatic. It is better to take than salicylic acid, which deranges the stomach. The salicylic acid of the salicylate (salol), however, is, after all, the effective agent, but the decomposition necessary to set free that acid from its combination with the phenol only takes place when the dose of salol reaches the duodenum, and consequently only after it has passed through the stomach. "*Antifebrine*" is the second therapeutic agent exhibited; its true name is *acetanilide*. The therapeutic name indicates its use.

GROUP VII.—DYES AND COLOURING MATTERS FROM OTHER SOURCES THAN COAL-TAR.

Of colouring matters or other principles, the chemical constitution of which is still unknown to us, we have those contained in most of the dye-woods—*e.g.*, logwood, fustic, quercitron bark, Persian berries, etc., and also tannic acid. (See Stand No. 796.) Many of these are of the very greatest importance to the textile colourist, and hence recourse must still be had to Nature's resources. It is interesting to note that nearly all the colouring matters above referred to are such as require the aid of mordants in order to develop and fix upon fabrics the colours they are capable of producing.

Millward & Cryer, 10, Greenwood Street, Manchester (No. 795).—The exhibit of this firm includes samples of indigo and the model of an indigo factory; specimens of the seed, plant, etc., and classified samples of indigo; specimens of refined indigo, and extract of indigo; patterns of fabrics dyed with indigo. Indigo is a colouring matter used as a dyestuff in India from the earliest times. Cloth dyed with indigo has been found in the old Egyptian tombs, and the process of preparing and manipulating the dye is accurately described by both Pliny and Dioscorides. The chief source of East Indian indigo is the *Indigofera tinctoria*, an herbaceous plant raised from seed, of which a sample is exhibited, which is sown in either spring or autumn. The plant grows with a single stalk to a height of about 3ft. 6in., and about the thickness of a finger. It is usually cut for the first time in June or July, and a second, or even a third cutting obtained later in the year. The number of leaves which the plant puts forth determines the value of the crop, as it is in the leaves that the colouring principle is chiefly contained. The crude mode of manufacture carried on in Bengal at the present day coincides exactly with the description of the processes given by Pliny and Dioscorides. When the leaves arrive at a proper degree of maturity the plants must be speedily gathered, and each cutting rapidly executed during the night, for the scorching sun would wither the branches and injure the produce. A great many hands are employed in the gathering process, and the surrounding villages are all requisitioned. The workmen are dispersed in the fields at midnight, and in the morning the produce of the harvest is deposited in stone troughs previously filled with water. Under the influence of the sun's rays fermentation soon takes place, and after about 48 hours the liquid is drawn off into shallow vats. Here it is beaten about by means of oars by the natives, who enter the vats, the object being to expose the liquid as much as possible to the action of the air. During this process the greenish yellow fermented extract from the leaves assumes a deep blue or almost black colour. The liquid is allowed to stand, and the indigo blue which has been formed gradually settles to the bottom as a fine powder. The supernatant liquid is drawn off and the indigo precipitate is boiled with water in metal vats in order to prevent further fermentation, which would injure the indigo itself. The indigo paste is then drained in filters, and the dark blue clay-like mass is cut into cubes, dried in open-air sheds, packed into chests and sent to the Calcutta market.

The fresh leaf of the indigo plant does not contain indigo, but a colour-yielding principle called *Indican*. Under the influence of the fermentation and the subsequent oxidation this colourless or faintly-coloured and soluble indican is decomposed or split up into glucose and indigo blue. The former remains dissolved in the liquid, while the latter, being insoluble, is precipitated in the beating or oxidation vats as described. From Allahabad eastward vast districts are to be found in which this forms almost the sole product manufactured. Oude, Tirhoot, Upper Behar, and a large area of Bengal are almost entirely in the hands of the indigo planters. The average annual production of East Indian indigo during the last 18 years may be placed at 120,000 maunds (about 74lb. to the factory maund), and the value over two millions sterling. The price of indigo has ranged within the same period, for fine Bengal and Tirhoot, from 8s. 6d. per lb. in 1870, when the crop was 92,000 maunds, to 5s. 3d. per lb. in 1878, when the crop reached 155,000 maunds, and is largely governed by the abundance or paucity of the crop, which in its turn is influenced by the monsoon or rainy season. Although the main supply of indigo is furnished from East India (consisting of Bengal, Tirhoot, Benares, Oude, Kurpah, Madras, and Bimlipatam qualities), yet there are also some considerable imports from Guatemala, from Caraccas in South America, and, in addition, from Java and some little from Manilla, the capital of Luzon, in the Philippine Islands; but all these last named occupy relatively a subordinate position. Recent experiments by R. C. Phillips have also shown that indigo can be easily grown on the West Coast of Africa, near the Congo.

E. D. Milnes & Brother, Lumn Mills, Lancashire (No. 796).—The main products exhibited by this firm are extracts used in dyeing, calico printing, and tanning of their own manufacture; also the raw materials from which such extracts are prepared; moreover, a number of chemicals and drysalteries employed in the same industries. The extracts exhibited comprise those of logwood, fustic, quercitron bark, Persian berries, sapanwood, sumac leaves, myrabolams, galls, divi divi, valonia, chestnut, oak bark, quebracho, and larch bark. The annual consumption of these articles in the United Kingdom already amounts to thousands of tons, and continues to increase rapidly. These extracts are simply aqueous decoctions of the above-mentioned vegetable products evaporated to the requisite consistency with special precautions; they are now obtained in a state of excellence formerly unattainable, and promise ere long to entirely displace the dyewoods and other raw materials from which they are prepared. The improvements effected consist mainly in the adoption of improved mechanical means for ensuring a thoroughly complete extraction of all valuable ingredients, and prevention of any deterioration or composition during both extraction and evaporation. This end is accomplished by the use of vacuum pans, in which the extraction can be effected at lower temperatures. Specimens of cloth dyed and printed with the extracts, etc., are shown in the same case, as well as fine examples of dyewoods.

Bourgeois Aîné, Rue de Caire, Paris; agent, Alfred Hallam, Post Office, Peel Causeway, Altrincham (No. 798).—The exhibit of this firm is composed chiefly of superfine colours for designers and engravers to calico printers. The colours are made up in five forms—viz., in tube, baton, flake, paste, and powder, and it is claimed for them that they are especially brilliant and opaque, and will work one over the other without loss of tone. These are the colours used in France in the production of the calico-print designs, etc., so well known in this district. A selection of drawing materials as used by designers is also shown.

GROUP IV.—LAKES, PIGMENTS, PAINTS AND VARNISHES.

Rawlins & Son, Brook Works, Rainhill, Prescot (No. 753).—A fine exhibit comprising the raw materials used in the manufacture of ultramarine, ultramarine in its intermediate stages, known as "raw ultramarine," "settled ultramarine," and "dried pulp ultramarine"; the finished ultramarine, and various manufactured goods illustrating its application in various industries; the raw materials used in the manufacture of "smalts," the fused cobalt glass or smalts in the intermediate stage, and the finished article ready for the market, together with manufactured goods illustrating its use.

Charles Scheu, 2, Cumberland Street, Manchester; and 65, West Regent Street, Glasgow (No. 754), exhibits very fine specimens of ultramarine colours, blue, green and violet, and the raw material used in their preparation; also a model of the form of furnace used in the ultramarine manufacture.

Robert Ingham Clark & Co., West Ham Abbey, and Leadenhall House, London, E.C. (No. 775).—A variety of varnishes for coachbuilders, decorators, heald manufacturers, etc., also carriage spokes, panels, and healds coated with these varnishes. An interesting collection is shown of fossil gums and resins used in the manufacture of varnishes, including gum amber from the shores of the Baltic, gum mastic from the island of Chois, gum kauri from New Zealand, gum animi from Zanzibar and Demerara, also gums from the interior of Africa—*e.g.*, Angola, Benguela, Sierra Leone, and red Angola copals, also gum copal from South America. Amongst these specimens are two which merit special notice—*i.e.*, a mass of gum kauri from New Zealand weighing about 200lb., and a mass of animi from Demerara containing embedded in its midst, a large number of ants and other insects. Both these pieces of gum are said to be the largest of their kind yet discovered.

William Pakeman, Manchester Road, Stockport (No. 756)—Specimens of mineral and vegetable pigment colours for the use of calico printers; also bronze powders and colours for paper stainers, printers, and manufacturers, all guaranteed free from arsenic; lakes and mineral colours for lithographic inks, etc.

Henry Crookes, A.R.S.M., M.S.T.E., 4, Westminster Chambers, London, S.W. (No. 757).—Shows a heat-indicating paint and some of its applications. The paint, which is a specially prepared iodide of mercury, or contains that substance, takes its name from the property it has of changing colour when heated to a certain temperature; the point at which the change takes place can be varied between 140 and 170° F. by certain modifications in the manufacture. Its principal use is to show when bearings of machinery or other surfaces liable to become overheated have reached a temperature which may be a source of danger; at such a point the paint changes its colour from a bright red to a dark chocolate. When allowed to cool it resumes its red colour, and this change takes place whenever the paint is heated and cooled. As examples of its application two flat-irons are exhibited, one painted a bright red, showing the colour of the paint at a low temperature; the other painted dark brown—*i.e.*, the colour which the paint assumes when the temperature rises over 150° Fahrenheit. Another application claimed for this paint is that it can be used for painting coils of wire through which electric currents have to pass; when the current exceeds a certain limit, the coil will become heated and the paint will change colour, thus indicating the rise of temperature.

Jos. B. **Freeman** & Co., Grove Works, Lombard Road, Battersea, London (No. 758), exhibit a kiosk painted with their patent non-poisonous white lead, also samples of the lead, and boards painted with it and subjected to the action of sulphurous fumes. This non-poisonous white lead consists mainly of zinc oxide and lead sulphate, specially prepared from metallic lead, mixed together, and finely ground under great pressure. Many attempts had previously been made to utilise lead sulphate as a pigment, but without success, the product being quite useless, possessing neither the necessary density, body, nor opacity. Moreover, a large quantity of oil is required in grinding it, and as a paint it is what painters term "slimy," and works very badly under the brush. The difficulties were finally overcome by adding about 25 per cent. of zinc oxide (in itself a substance possessing neither good body nor density), and subjecting the mixture to great friction and pressure under heavy edge runners. A complete change in the character of the substances employed is thus effected, such indeed as it would appear impossible to produce by any mere process of mixing, and a pigment possessing great density, opacity, and whiteness is the result. The whiteness is said to be greater than that of the finest white lead made by the Dutch process. As regards density, 3 cubic feet of lead sulphate weighing 170lb. per cubic foot and 1 cubic foot of zinc oxide weighing 58lb. when mixed together and treated by the above process yield the pigment in question, weighing over 200lb. per cubic foot. According to Professor Church, when surfaces coated with this paint are submitted for various periods to the action of air containing sulphuretted hydrogen, they remain unaffected, or are "only very slightly tinged;" when they are excluded from light for some time the paint does not turn yellow or buff—a well-known objection to the use of white lead.

Donald Macpherson & Co., Manchester Paint and Colour Works, Knott Mill, Manchester; and 106, Cannon Street, London (No. 761).—The articles exhibited are a kiosk illustrating the use of Foochow enamels, metallic paints for exterior, quick-drying enamels that require no stoving, and vases, bricks, and timber enamelled with the quick-drying Chinese enamels with which tea trays and papier-maché articles imported from China are coated. The paints have on drying an extremely hard, tough, glossy surface, are not affected by sulphuretted hydrogen, and will not crack, blister, or scale off. They are suitable for machinists, japanners, and other manufacturers who have to turn out goods as soon as finished, and yet require a highly enamelled surface.

Goadsby & Co.: office, 2, 4 and 6, Albert Bridge; works, Newton Heath, Manchester (No. 762), exhibit colours, paints, varnishes, etc., amongst which are a concentrated oil drier, used by linseed oil boilers and manufacturers of tarpaulin, oilcloth, and linoleum; it is said that 1 part of this drier to 20 parts of linseed oil makes it dry hard in about eight to twelve hours. Terebene is used by painters, decorators, etc., as a drier. Engine green is used for locomotive and other engines; it is stated that this paint does not change colour or crack even when heated by means of super-heated steam. Vermillionette is a substitute for vermillion, largely used at a time when genuine vermillion was high in price. It is a chromate of lead prepared in a special manner. A large number of prepared lakes of eosin are also called vermillionette by some makers, but though a good imitation in point of colour they do not stand exposure This colour is used by railway companies, manufacturers of printing inks, agricultural implements, etc. Goadsby & Co.'s paint detergent is used for washing down and cleaning off old paint and grease, and for washing lithographic stones and type. Varnish enamel paint, a combined colour and varnish, household paint ready for use, and peroxide of iron paint are also shown.

Griffiths Brothers & Co., 6, Dashwood House, 9, New Broad Street, London, E.C. (No. 763).—The exhibits of this firm comprise aquol, a washable water paint; vitros bath enamel, for enamelling baths, etc., without stoving: and Griffith's patent zinc white (sulphide of zinc). It is claimed for this latter article that besides being non-poisonous "it covers one-third more than white lead and 100 per cent. more than zinc oxide." It is said to have no chemical action upon metals, is not discoloured by foul gases or bilge water, and is fireproof and unaffected by a red heat. It is also said that the most delicate tints or "tones" can be produced with it not possible with lead. This zinc white is produced as follows:—Either zinc chloride or sulphate is precipitated by a soluble sulphide—sodium, calcium, and barium sulphides all having been used for the purpose—and precautions are taken lest any iron that may be contained in small quantities as an impurity in the zinc solution should be precipitated with the sulphide of zinc. The precipitate, being collected and dried, is calcined in a furnace, then raked out, whilst quite hot, into vats of cold water, when it is levigated and dried. An analysis by Dr. T. L. Phipson shows that the pigment consists of an oxysulphide of zinc. Pyrodene is a fire-proof paint for fireproofing wood, canvas, etc. It may be mentioned that all the timberwork of the Fine Arts Section of the Exhibition has been treated with Griffith's pyrodene and painted with aquol.

F. & C. **Osler**, Birmingham and London (No. 768A).—This firm shows an ornate glass fountain, playing, according to a device of Mr. I. Levinstein, fluorescent water—*i.e.*, a faintly alkaline solution of fluorescein. The basin is painted with black and white bands, and shows the fluorescence remarkably well, the water appearing yellow by reason of the light transmitted from the white bands, and sea-green when the black bands absorb the light. The non-poisonous nature of the fluorescein is illustrated by the fact that goldfish have been living in the water for two months.

GROUP V.—BLEACHED AND COLOURED FIBRE.

Ermen & **Roby**, Nassau Mills, Patricroft; and 14, College Land, Manchester (No. 771).—This exhibit of cotton yarns is divided into three groups—1, mending, knitting, embroidery, and crotchet cottons; 2, polished cotton; 3, sewing cotton on spools and in balls:—

1. The mending and knitting cotton being principally used for hosiery, it is important that the colours should be fast, so as to resist washing and exposure to the light Consequently the most permanent dyes are selected for these yarns, such as turkey reds, indigo blues, aniline blacks, etc. A large quantity of bleached knitting cotton is used. The same remarks apply in great measure to the embroidery and crotchet cottons; the colours are made as fast as possible. Crochet cottons are principally used in white.

2. Godfrey Ermen, late partner in this firm, was the first inventor and patentee of the process of polishing or glazing cotton thread, and the firm has made this article a speciality ever since. Polished thread is shown, wound on reels of various sizes. The aim of the firm has always been to combine elasticity and softness with strength, in order to produce the most suitable thread both for the sewing machine and for hand sewing.

This exhibit as a whole is rendered something more than striking—in fact almost magnificent—by being itself incorporated in another representation. In short, the items above given are incorporated in a model of the famous monument at Athens, erected B.C. 335, by Lysikrates to celebrate his victory for the best chorus at a dramatic contest. It takes the form of a small temple in the Corinthian style, showing the finest and purest style of Greek art. The height of the original is 35ft., Messrs. Ermen and Roby's *fac-simile* being 18½ft.

Ch. Weber & Co., Thann, Alsace (778).—The exhibit of this firm consists of cotton yarns, slubbings, rovings, etc., both dyed and bleached, in the cop, spools and bobbins. The process of dyeing and bleaching the yarn in this form is worked on the Continent, and as it dispenses with the operation of reeling, pirn-winding, etc., effects economy in space, plant, time, and labour. It is also claimed that when yarns are dyed in this form there is less waste and no shrinkage or loss in length.

Select Exhibit of Committee of Section III., collected by J. J. Hummel, Yorkshire College (No. 779).—A most valuable and instructive exhibit, collected and arranged with very great skill and considerable artistic effect. Messrs. E. Potter & Co., we are informed, supplied much of this valuable exhibit of calico prints, and placed their whole collection at Professor Hummel's disposal. Messrs. F. W. Grafton also contributed liberally. An illustration of the gradual advance in artistic design and colouring since 1785 to the present day is shown, the equal of which has rarely been seen and probably does not exist outside that belonging to the Société Industrielle de Mulhouse. A series of woollen patterns dyed with the natural colouring matters, and also with the artificial (coal-tar) colouring matters, is shown; also compound shades, dyed with mixtures of three colouring matters, of each class. Besides these, patterns of cotton and silk dyed with coal-tar colours obtained by Goppelsroeder's electrical method, and the apparatus by which aniline black is produced on cotton, and discharge white on indigo blue, by the aid of electricity.

William M'Farlane, Miller's Brook Dyeworks, Heywood, near Manchester (No. 780).—This firm exhibits specimens of dyed cotton yarns used in the manufacture of coloured textiles at home and abroad—*e.g.*, for dhootie, khakee, drill, and general trade, also specimens of dyed cotton, lace and lace yarns. The yarn is dyed in various forms—in hanks or bundles and in ball warps and chains. A special feature in this exhibit is the alizarin red dyed on yarn in the form of ball warp and chain. Until recently all yarn was dyed in the form of hanks, and the operations were almost entirely manual. The introduction of improved machinery, however, has made it possible to dye yarn in the form of ball warps and chains, and this method forms now a most important branch of the cotton yarn dyeing industry.

Select Exhibit of Committee of Section III., collected by Watson Smith (No. 781).

1. A series of silks dyed with coal-tar colours in all the prismatic shades according to a graduated system. These specimens were dyed by the eminent French firm, Marnas, Bonnet et Fils.

2. A set of specimens of fabrics printed and dyed in indophenol by the firm of H. Koechlin, of Lorrach, Alsace, as well as the indophenol white and blue in paste and powder. This dye was formerly proposed as a substitute for indigo, but its non-resistance to acids is much against it. Specimens of all the raw materials used in the preparation of the indophenol blue are shown, as prepared by Dr. Otto N. Witt.

3. A specimen of murexide, a crimson colouring matter, formerly prepared from guano, is exhibited, as originally manufactured by the late Robert Rumney, of Manchester, who first introduced the colouring matter into England. The discovery of magenta quickly crushed any hope of extending the use of this fugitive but beautiful red. A piece of cotton cloth printed with murexide is exposed, and though full and bright when first placed in the case, is now much faded.

4. Piece of calico printed with alizarin on different mordants: the alizarin used being a 20 per cent. paste prepared from anthracene, made in South Russia from Baku petroleum residuum, by passing through red-hot pipes filled with charcoal or coke. (See exhibit No. 733, Messrs. Ragosine & Co.) Specimens of the residuum and of the alizarin paste are also shown.

5. One pound each of the several kinds of coal used in the Manchester Gasworks for the mixture adopted in charging the gas retorts is shown, and by the side of these specimens a parti-coloured strip of cloth dyed with the exact amounts of the coal-tar colours that could be prepared from the products of the tar from one pound of such coal. The dyed strip of cloth thus strikingly represents the amount of colouring power in one pound of Lancashire gas coal.

6. Watson Smith exhibits chemically pure specimens of the aromatic hydrocarbon series, and of phenols contained in coal-tar.

7. The amount of bisulphide of carbon formed in coal-gas making varies directly with the temperature of distillation adopted, and hence where, as in London, coal is dear and the gas supply required very large, the highest temperatures are employed. A maximum of carbon bisulphide will of necessity be formed in such cases and appear in the tar. Watson Smith, by fractionally distilling a quantity of rectified benzene, obtained from the "first-runnings" of London coal-tar, succeeded in separating no less than 6 per cent. of pure bisulphide of carbon. A specimen of this bisulphide is exhibited, together with the original benzene from which it was isolated. A small specimen of chemically pure benzene prepared by passing phenol over red-hot iron borings is shown. Even ordinary alcohol is contained in some specimens of London rectified benzenes, formed by the action of the sulphuric acid used in the purification, on a certain quantity of olefiant gas dissolved in the crude benzene and the subsequent action of steam in the final distillation process. A specimen of such alcohol, separated by Dr. Otto N. Witt, is shown.

8. A specimen of sulphate of ammonia as obtained from the products condensed from the blast furnaces of the Gartsherrie Ironworks is shown, and also specimens of the tar and various hydrocarbons extracted from it by Watson Smith, both paraffins and members of the benzene series.

9. In order to prepare naphtha and acetic acid from wood, the latter must be submitted to a destructive distillation at a comparatively low temperature. Oak cropwood is used for this purpose, and the distillation takes place in cast or wrought iron retorts. Specimens of oak cropwood such as is actually charged into the wood retorts, and of charcoal left as a residue, are exhibited, and besides these, specimens of crude tar and acid, and also of the purified products, are shown.

It is generally said that pure commercial methyl alcohol made from wood must be obtained from Germany, as it is not prepared in this country. However, a specimen is shown here of a pure product made by a Glasgow firm for the use of dye and colour makers.

10. An exceedingly fine specimen of the Boghead cannel coal, now quite extinct, but from which Dr. James Young first prepared paraffin, is shown, with one of the Boghead shale at present used, and a collection of naphthas, burning oils, paraffin waxes, etc., prepared from the Scotch shale.

In a horizontal case are shown specimens of raw cotton in the pod, and even with the pod attached to the branches from the cotton tree, raw picked cotton, cotton silk of various kinds in the pod and picked, raw jute and jute fibres, China grass, various dyewoods, several species of indigo plant and colouring matter, with seeds of the *Indigofera tinctoria*. On the outside of the case the entire trunk of a cinchona tree is shown; also a set of cinchona barks, collection of twenty commercial gums, one of resins, and specimens of seed, stick and shell lac; Chinese insect wax, nutmeg in shell and fruit, cocaine plants and fruit, with active principles.

An interesting set of specimens illustrating the phosphate trade, and consisting of fine specimens of coprolites, apatites, etc., from the United States, is exhibited. Finally, a Chinese opium-smoker's tray is shown, with pipe and all the apparatus of the opium slave. Opium consisting of large balls, the commercial form, is also exhibited.

HENRY NEWALL & SONS, 10, Marsden Street, Manchester (782), exhibit wood pulps prepared by mechanical and by chemical processes for the manufacture of paper; also wood flour, used in making linoleum, wall decorations, and other fabrics, and in the manufacture of explosives. A special feature in the exhibit is the chemically prepared wood pulp, which shows a fibre much longer and stronger than that prepared by the mechanical process. The manufacture of wood pulp was commenced in Norway about the year 1870, from 500 to 600 tons being exported in that year. The industry has increased very rapidly, the production last year being about 100,000 tons. At first the wood pulp made by the mechanical or grinding process, and possessing very little fibre, was the only kind produced, but within the last few years chemical processes have almost superseded this method. By treating the wood with sodium sulphite a pulp with a long fibre suitable for better class papers is obtained, whilst mechanical pulp is only used for newspapers, wall papers, etc. A large amount of wood pulp is produced in Germany, but it is mostly consumed there, very little being exported. It is estimated that this year the production of this article will amount to 150,000 tons, valued at about £350,000.

GROUP VI.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

MESSRS. JAMES WOOLLEY, SONS & CO., Manchester (No. 785), exhibit an interesting collection o drugs of vegetable origin recently adopted as remedia agents, and solid and liquid preparations thereof adapted for medicinal use. Amongst the new remedies shown of vegetable origin are cocaine and strophanthus; whilst amongst those of coal-tar origin are antipyrine, antifebrine, and salol. Everyone has heard of the deadly Kombé arrow poison, used by the natives of the African coast. This poison is the extract of the seeds of the Strophanthus plant, and the chemical principle, a glucoside, is termed strophanthin. Mr. William Elborne, of the Owens College, has succeeded in isolating this poisonous glucoside in a state of purity. In small doses it is being used extensively in medicine as a valuable remedy in certain forms of heart disease. There are also specimens of various solid and fluid extracts, besides preparations of cinchona, opium, and nux vomica as directed by the "British Pharmacopœia" of 1885 to contain a definite proportion of active principle. The oleates shown are of considerable interest, and are prepared both by double decomposition and direct combination. They are principally used in dermatology. Besides these are to be seen ointments, pills coated by a soluble covering so as to temporarily conceal taste and odour, and a specially prepared cod liver oil, with emulsions of the same, etc.

THOMAS CHRISTY & CO., 25, Lime Street, London, E.C. (No. 787).—An interesting collection, containing in the dried state a variety of the plants, nuts, fruit, etc., from which the principal medicaments, extracts, alkaloids and essences—as well as foods—of vegetable origin are obtained. Besides these are also shown the prepared essences and other medicaments. It may not occur to those who admire the large quantities of rare alkaloids and extract preparations exhibited in some of the neighbouring showcases to Messrs. Christy's to inquire, "Where are the raw plants and drugs, nuts, roots, etc., obtained, from which these preparations are made?" The reply is, Messrs. Thomas Christy & Co. is one of the few firms in existence for collecting these. Amongst pharmacologists Mr. Thomas Christy's interesting periodical, "New Plants and Drugs," is well known, but a staff of experts is kept employed in foreign lands whose duty it is to investigate and report to headquarters, with the object of bringing new drugs and extracts to light. This firm has now a very considerable stock of raw plants and drugs, which, being convinced must be used some time, they offer to supply samples of to practical experimenters and scientific investigators for their researches. The exhibit is a collection of raw and manufactured drugs and their preparations, menthol and menthol cones, barks of various kinds, fibres, different specimens of gutta-percha, rubbers, tanning barks, dyewoods, etc., together with many other materials and finished products.

MESSRS. HOWARDS & SONS, Stratford, London, E. (No. 792).—Messrs. Howards & Sons have probably done more than any firm in practical experimental research and commercial enterprise to place fine quinine, as well as other preparations, at a moderate price in the market. Exceedingly fine and tastefully arranged specimens of cinchona barks and alkaloids are exhibited, as well as an interesting variety of organic acids and alkaloids used in pharmacy. The samples shown illustrate the great change which the introduction of cultivated bark has brought about in the quinine industry. The alkaloids exhibited by this firm are extremely pure. A beautifully crystallised specimen of iodoform is exhibited as the manufacture of Messrs. Howards. Specimens of coca leaves, of the cocaïne alkaloids and their salts, and of benzoyl-ecgonine, obtained by heating cocaïne with concentrated hydrochloric acid, are also shown.

E. MERCK, Darmstadt, London and New York (No. 788).—This firm, so well known for pharmaceutical preparations, alkaloids, and similar chemicals, makes a fine display. Without attempting to describe all the features of interest in the showcase of this firm, some preparations and substances found useful in the case of the most recent remedial efforts, may be desirable. In the first place, a colourless syrupy liquid is shown, *Lactic acid. alb.*, of specific gravity 1·21. It has been lately recommended by Mosetig-Moorhof for the purpose of destroying morbid and unnatural growths and formations. Internally used, it is recommended for diabetes, 5 : 300 per diem. A splendid specimen of *Aconitine nitrate cryst.* (Merck) is also to be seen. It is prepared from *aconitum napellus* by Duquesnel's method. The salt appears in the form of colourless crystals, soluble in water and alcohol. Its action on the animal economy is much more intense than that of the amorphous aconitine; it is, in fact, one of the strongest poisons known. The consumption in England and France is very considerable. Another specimen of great interest for the physician and student of medicine is that of *Apomorphine hydrochloride cryst.* It is a salt in the form of colourless crystals, soluble both in water and alcohol. The solution on exposure to air and light becomes gradually green, but the change is said not to diminish its physiological effect. Apomorphine is a certain emetic, 0·004 to 0·01grm., causing vomiting within six minutes. A valuable principle is the glucoside *Arbutin*, which is exhibited in white crystals. It is contained, along with tannic acid, gallic acid, and ursone, in the leaves of *Uva ursi.* Arbutin is easily soluble in water, but less so in alcohol, and it has a bitter taste. Even large doses do not produce fatal effects. It is a valuable medicine in the treatment of inflammatory catarrh of the bladder. The usual dose is three to four grms. in solution or as powder. Specimens of *Atropine* and its *sulphate*, of rare beauty as well as bulk, are shown. *Atropine*, melting at 239° Fahr. (Merck), absolutely pure, and especially free from daturine (so-called light atropine). The high melting point proves this. Moreover, its purity is indicated by its being in very hard, bright, and heavy crystals. Preparations containing daturine have a much lower melting point (about 223 to 226° Fahr.), and are never seen in such fine crystals as those which are free from it. *Atropine sulphate white cryst. neutral* (Merck): Extremely pure and absolutely neutral. A solution of 1 in 1000 produces mydriasis after 15 minutes; solutions of 1 in 200 have the same effect in from five to 10 minutes. The internal use of atropine as anti-spasmodic, anodyne, and sedative, as well as a means for limiting certain secretions, has increased, and especially since atropine has been recognised as a powerful *antagonist* to different narcotic poisons, such as morphine, digitaline, prussic acid, etc. Thus the most reliable antidote to atropine would be repeated injections of morphia, accompanied with skin excitation and artificial respiration. This property and fact of the antagonism of symptoms produced by certain alkaloids and principles is very singular, and likely to prove of great value in medical practice. It was referred to by Professor Leech at the Pharmaceutical Conference recently held in Manchester. Since the increase in demand for *Belladonna* root, and the consequent rise in price, the cheaper root of a kind of scopolia (false belladonna) has been extensively placed in the market, and has found a ready sale. The fact of many makes of atropia sulphate having varying melting points is thus accounted for. An interesting alkaloid shown is *Berberine*. It is found in the *Berberis vulgaris L.*, and also in many other plants. The specimen, a very fine one, is in glittering reddish brown crystalline scales, which begin to sublime at 392° F. The alkaloid is not readily soluble in cold water, but easily soluble in hot water and in alcohol, and nearly insoluble in ether and carbon bisulphide. The salts, hydrochloride and phosphate of *Berberine*, which are also exhibited, are readily soluble and are easily absorbed. The dose for indigestion and diarrhœa is about one grm. per diem. It is used also in cases of sickness during pregnancy and malaria.

A beautiful series of salts of *Caffeïne* is shown—*e.g.*, the benzoate, hydrobromide, hydrochloride, nitrate, salicylate, sulphate, valerianate, sodio-benzoate containing 45·8 per cent. of caffeine, sodio-cinnamylate with 62·5 per cent. of caffeine, etc. Mr. Merck made an interesting report on these salts and double salts as soon as he had succeeded in producing them in the form of true salts, especially the easily soluble double ones, instead of the indefinite mixtures hitherto known. According to Merck, Riegel and other investigators proposed these new compounds as substitutes for *digitalis*—a proposal of the greatest importance to the medical world. The effect of the injection of caffeine is perceived at once, and collateral effects, especially those of a cumulative nature, are absolutely excluded.

Camphor Monobromide and Dibromide.—Of these compounds the monobromide is chiefly in demand. It is but slightly soluble in water and glycerine. As sedatives these preparations are used for epilepsy (subcutaneously 0·1grm. dissolved in oil), for chorea, migraine, nervous palpitations of the heart (internally 0·1grm. to 0·5grm. in wafers); whilst in cases of delirium tremens doses of 1·5grm. are given. Fine specimens are shown of both these salts. An important compound, also shown, is Merck's *Cannabine tannate.* It serves in many respects successfully as a substitute for morphia, and together with the preparation named *Cannabinone* (a 10 per cent. trituration) we have two valuable hypnotics showing no unpleasant after-effects. The raw material is obtained from the *Cannabis indica*, a variety of the *Cannabis sativo L.* (*Uticaceæ*). The tannate is given in doses of 0·25grm. to 0·1grm.; in cases of delirium 1·5grm. The cannabinone (pure) is administered in doses of 0·05grm. to 0·1grm. The rare metal *Cerium*, in the form of its oxalic acid salt, even serves as a valuable medicament, and a sample of pure cerium oxalate is to be seen as a white granular powder, insoluble in water and alcohol, but soluble in hydrochloric acid. The dose is 0·05grm. to 0·15grm. It is used as an antidote to catarrhal affections of the stomach and bowels, sickness during pregnancy, and epilepsy. *Chrysarobin* prepared from *Goa powder* is another specimen of interest. This preparation is absorbed by the skin, and has thereby a stimulating effect. It produces vomiting and diarrhœa; and has a stimulating effect on the kidneys; this is the case also when applied externally. It is chiefly used for Psoriasis.

Among the finest specimens are the *Cocaïne preparations*, of which the hydrochloride and salicylate are shown. The hydrochloride is granular, crystalline, and white, and free from every impurity. Dr. Karl Koller, of Vienna, was the first to draw attention to the local anæsthetic properties of cocaïne, and to turn them to account. Dr. Brettauer, at Koller's request, explained and exemplified the discovery on the 17th and 18th September, 1884, before the Ophthalmological Society of Heidelberg. It is proposed to use the cocaïne in various ways. Emmert in the treatment of the eye proposes to use it as a salve with vaseline; Fodor to use it alone. To make its solutions keep well, many additions have been proposed. The simplest is an addition of glycerine. In tuberculous disorders of the air passages Meyer-Hüni recommends inhalations of cocaïne. Most painful injections of corrosive sublimate are made quite bearable by first adding to the mercurial solution only 0·05grm. of cocaïne per dose. Randolph and Dixon commend a concentrated solution of cocaïne hydrochloride in nitric acid as a painless causticising agent; the wound to be bound up with a bandage covered with cocaine salicylate. The best antidote against poisoning with cocaine is amyl nitrite, according to Schilling. When cocaine is heated with strong hydrochloric acid it decomposes, forming benzoic acid, methyl alcohol, and *Ecgonine*, a specimen of which is exhibited. *Ecgonine* was first discovered in Merck's laboratory.

Specimens of pure crystallised *Codeïne*, its soluble phosphate and salicylate, much in favour on account of stability of the solutions, are shown. The phosphate dissolves in four parts of water, and the solution, subcutaneously injected, produces no pain or reaction at the place of incision. The dose of the phosphate for diabetes Merck gives as 0·06grm. three times daily, increasing by 0·06grm. every eight days up to 0·54grm.; cod liver oil is taken at the same time. *Codeïne* is a methylmorphine.

Another useful vegeto-alkaloid, exhibited in fine crystalline condition, is *Colchicine*. It is found in all parts of the meadow saffron (*Colchicum autumnale L.*), and is a very strong poison. In doses of 0·0005 up to 0·002grm. two or three times a day it is a remedy for gout and rheumatism. For subcutaneous injection it is not to be recommended. For complaints of a convulsive nature, spasmus glottidis, tussis convulsiva, asthma, etc., a valuable remedy is coniine in the form of its salts. *Coniine* is an alkaloid of the *Conium maculatum L.*, which plant also contains two other alkaloids, conydrine and methyl-coniine. Our knowledge of the chemical constitution of coniine we owe to Hofmann and Ladenburg. Coniine has been recommended and used by Murawelff for toothache caused by decayed teeth: the pain ceases through the paralysis of the nerves. Of course the alkaloid is directly applied to the exposed nerve. Very remarkable is the antagonism of certain highly poisonous substances: such antagonism exists between coniine and brucine, for coniine, as Hugo Schulz has shown, paralyses the symptoms of brucine poisoning. Pure coniine is a colourless oily liquid, whilst the salts take the crystalline form. The hydrochloride crystallises best. The hydrobromide is a very constant compound, and contains a definite quantity of coniine. It is readily soluble in water, and thus easy to administer. The dose of coniine hydrobromide is 0·001 to 0·02grm. several times daily. Fine specimens of the above two salts are to be seen in the exhibit.

Cotoïne and *Paracotoïne* are very interesting bodies about which as yet very little is chemically known. Messrs. Merck show fine specimens of both in the pure state. Since the year 1873, various barks have been introduced into the market, which it was believed would replace the quinine or cinchona barks. These drugs were brought from Bolivia, though still more recently the old forests of Brazil have been made to furnish them. The barks mentioned appear to come from a species of *Rubiaceæ*. However, the crystallisable principle cotoïne was first isolated by Hesse, and it has the composition $C_{22}H_{18}O_6$. It is soluble with difficulty in cold water, easily in hot, also in alcohol and ether. Cotoïne and Paracotoïne are styptics, and have been found useful against diarrhœa and excessive perspiration. Particularly must cotoïne be considered as a preventive of diarrhœa in children and in cases of phthisis. The doses vary from 0·05 to 0·1grm. for cotoïne and 0·1 to 0·2grm. for paracotoïne. The relations of cotoïne and paracotoïne to each other seem to be remarkably similar to those of quinine and cinchonine.

Another rival of quinine is *Ditaine*, of which a well crystallised specimen is shown. It is a crystalline substance obtained from *Alstonia scholaris L.*, an apocynea found in the East Indian Islands. Ditaïne, it is stated, has effects similar to those of quinine, and is recommended against intermittent fevers.

A finely crystallised specimen of *Ethoxy-caffeïne* is exhibited. It takes the form of needle-shaped crystals, melting at 284° F., very little soluble in alcohol and ether, insoluble in water, and of very basic properties. The dose varies from 0·25 to 1grm. per diem. Ethoxy-caffeine is a sedative and a narcotic, and is of value in the treatment of migraine in cases where other medicines do not produce any effect.

Another very pure and beautiful preparation is *Merck's Helenine*. This is shown in the absolutely pure state, melting at 230° F., and consisting of colourless neutral crystalline needles. At one time an impure so-called helenine was used, and consisted mainly of powdered alant root. However, serious, even fatal, results followed the use of it, owing to other and foreign substances present. Merck now offers only the absolutely pure alkaloid. It is used for diseases of the respiratory organs, for reducing inflammation, and is said to speedily relieve chronic bronchitis.

Hydrastine (pure, crystallised), and *Hydrastine Tartrate* (pure, neutral).—The first of these interesting preparations is the alkaloid of the *Hydrastis Canadensis L.*, a ranunculacean plant found in North America. Pure hydrastine is almost insoluble in water, but the tartrate dissolves easily. In America hydrastine is recommended as an antiperiodic for fever with inclination to profuse diarrhœa, for certain diseases of the eye, of the skin, for hemorrhoids, etc. In Germany it is sometimes prescribed for its effect in contracting the uterus.

Hyoscyamine (pure and crystallised), from *Hyoscyamus niger*.—This is perhaps one of the most extraordinary of the alkaloids as regards the remarkable results in the treatment of diseases that are obtained with it. The specimens of the alkaloid and its salts, the hydrobromide and hydriodide, exhibited are perfectly pure. Hyoscyamine is isomeric with atropine and identical with daturine and duboisine. This preparation is used by oculists instead of atropine; subcutaneously as a hypnotic in cases of insanity, and as an antispasmodic in asthma, epilepsy, whooping-cough, chorea, etc. The dose as a hypnotic is up to 0·005grm. subcutaneously injected. *Pure Hyoscine* is amorphous and of a syrupy form, but its salts crystallise readily. The hydrobromide and hydriodide are in chief use as medicines. E. Merck produces both hyoscine and hyoscyamine on a large scale, and he claims that the articles sold in the market are generally of his preparation. The most wonderful feature in the properties of hyoscine is the power of tranquilising maniacs, and of all the remedies in use for this purpose it may be regarded as the most valuable on account of its prompt effect, and because it is not dangerous even to patients suffering in a high degree from heart disease. Experiments carried out by Professor R. Kobert and Dr. Sohr with hyoscine hydrochloride proved that the greater part of the hyoscine administered passes from the body through the kidneys. Doses of one milligramme of hyoscine applied subcutaneously increase the action of the heart and circulation, but have no influence on the respiration. The secretion of saliva is suspended by it, as also the action of the intestines due to nervous irritation. In therapeutics the effect of hyoscine on the healthy and the (mentally) diseased organism is of most particular importance: on the former, the effect is generally that of a narcotic, and on the latter, in all cases, the effect on excitable patients, even on raging lunatics, is sleep-producing and calming. Dr. Gamgee, F.R.S., late of the Victoria

University, told the writer that he had observed the effect of the subcutaneous injection of about 0·001grm. (between one and two hundredths of a grain) in the case of a maniac in a condition of which to say the strait-waistcoat and padded room were necessary would give but a mild notion of the frenzied state. That effect was a marvel; in a few seconds the patient being led away as tractable and harmless as a child, though with a stupefied and dazed expression of countenance. Of 101 subcutaneous injections of hyoscine hydrochloride in doses of ½ to 1 milligramme applied to a large number of patients in the Clinical Hospital for Mental Diseases at Dorpat during the months of July, August, September of 1886, not one failed to produce sleep, nor were in any case secondary effects observable. Almost in all kinds of diseases, accompanied by periods of excitement, either sleep or a calming effect had been produced, even when other means had been tried in vain, applied for the same purpose.

A useful preparation called pure *lacmoid*, in scales, is shown. It will be of interest to chemical analysts, as a substitute for litmus. It is extremely sensitive to acids and alkalis. A useful solution for testing is recommended by Merck, as follows:—0·5grm. lacmoid, 100cc. of water and 100cc. of alcohol of 96 per cent. strength.

Lithium Salts, the Carbonate, Hippurate, Citrate (crystallised), and Salicylate, are exhibited in great purity. The lithium salts have a more powerful diuretic effect than the salts of potassium.

Naphthalene.—Many people will look at this as a remarkable substance to propose as a medicine. If well purified, it is a valuable anti-diarrhoicum in cases of typhoid, diarrhœa, and intestinal complaints in case of phthisis. Not being absorbed by the bowels, this preparation has no general effect on the organism, but only on the mucous membrane of the bowels. Dose, up to 5grms. per diem.

Papaine.—This is a form of vegetable albumen capable of extraordinary powers of digestion, even greater than those of pepsine. It is obtained from the *Carica papaya L.* (*Papayacea*). One part of papaine peptonises and renders soluble 200 parts of blood-fibrin. It has been used very successfully for painting and so dissolving and removing the fatal membrane in cases of diphtheria. Merck states that most of the papaines in the market do not possess one-fourth the digestive power of his preparation.

Pilocarpine.—This alkaloid is exhibited in the pure state, and also in the form of salts, which are very fine examples as pharmaceutical preparations. The hydrobromide, hydrochloride, nitrate, and salicylate are shown, and also the pilocarpidine nitrate of Harnack-Merck. Pilocarpine is the alkaloid of the jaborandi leaves; it possesses a powerful diaphoretic salivating action. West recomends very small doses (0·005 to 0·01grm. subcutaneously) in cases of the nocturnal sweating of consumptive patients. Pilocarpidine was discovered in E. Merck's laboratory in the process of working upon a large quantity of jaborandi leaves. Pilocarpine and pilocarpidine produce the same physiological effect. This alkaloid has recently become of enhanced interest to chemists, since the mode of artificially preparing it by synthetical chemical processes has been discovered by two French chemists. Finally, magnificent specimens of strychnine in the pure crystalline state and of strychnine sulphate are exhibited. The best antidotes for this most deadly poison are paraldehyde and chloral hydrate. Fine specimens of *Veratrine* are shown. Used externally, the effect is that of a stimulant to the skin, whilst taken internally it acts as an antipyretic.

DR. THEODOR SCHUCHARDT, Goerlitz, Germany (No 790).—The following are specimens of special rarity and beauty in Dr. Schuchardt's exhibit:—*Metallic selenium*, its tetrachloride and tetrabromide; *Tellurium*, crystallised and sublimed, and its tetrachloride; fine specimens of *Germanium*, discovered by Clemens Winkler, with its sulphide and oxide; *Cerous sulphate*, crystallised with five molecules of water; *Yttrium nitrate*, crystallised; *Erbium nitrate*; metallic *Indium*, a magnificent specimen as a block, weighing 100 grammes, also its hexachloride, sulphate, hydroxide, and its double potassium chloride; *Gallium*, fine specimen of the metal, its ammonium alum, and other salts; *Thorium chloride*, *Tantalum chloride*, *Niobium chloride*, and an interesting specimen of crystallised *Osmic acid*. So much for the rare metals and their salts to be seen in this instructive cabinet. Amongst the organic preparations we note the following, of which it will not be easy to find similar examples, if examples at all, in the chemical collections and museums in this country:—α-Naphthoquinone and β-naphthoquinone (well crystallised); *Eupittonic acid*, the interesting colouring principle found in wood-naphtha and wood-tar. The following are derived from or contained in coal-tar:—Pyrene, together with its fine red picrate, so characteristic of it; chrysene, a magnificent specimen, pure white and crystalline; durene (tetramethyl-benzene), only recently discovered by K. E. Schulze in coal-tar; acenaphthene and pseudo-cumene, hydrocarbons of coal-tar. Thiophen and thiotolen, recently discovered by Victor Meyer. The phenol of thiotolen is also exhibited, together with a series of thiophen compounds, etc. α-α-Lutidine and α-γ-lutidine are finely exemplified; also the phenyl and tolyl pyrrols. Besides these are the following:—Crystallised sorbin and dextrose, galactose, inulin, a crystallised compound of dextrose with sodium chloride and a molecule of water; arabinose, inosite (crystallised), levulose, and maltose (crystallised). Amongst colouring matters are:—Orcein, dimethyl-*p*-phenylenediamine, tetramethyl-*p*-phenylenediamine, metaphenylenediamine, chlorophyll, phyllopurpurin, pyrrol red, etc.; whilst as specimens interesting to the pharmaceutical chemist are:—Hypnone (crystallised), glutamine hydrochloride, umbelliferone, terebene, sylvestrene, pinene, camphene (crystallised), limonene, borneol (artificial crystallised and natural crystallised), terebine hydrochloride, curarine hydrochloride, helenine (crystallised), tyrosine (crystallised), alloxan (crystallised), and finally tincture of strophanthus.

MESSRS. KAY BROTHERS, Lower Hillgate and St. Petersgate, Stockport (No. 794), exhibit a miscellaneous collection, comprising the following:—Simple and compound essences, extracts, etc., absorbent and antiseptic cotton wools—*e.g.*, pure absorbent, carbolised, sublimated, salicylated, and iodoformed. Glass valve tubes (Kay's patent). Disinfectants, a fusible cement for stone and iron work. Perfumery, syrups, medicinal extracts and essences of ginger, peppermint, sarsaparilla, taraxacum, and ergot. Among medicinal oils we note those of cod liver, castor, linseed, cotton seed, mustard seed, sweet almond, olive, sperm, and lard.

GRIMSHAW BROTHERS, Canal Chemical Works, Clayton, Manchester (No. 786).—This exhibit may be divided into three series:—

1. Zinc compounds used in manufactures and pharmacy, the chief of these being (*a*) chloride of zinc in the solid and liquid state, the former run hot into lead-lined casks for export (Messrs. Grimshaw were the first who made it largely in this form); (*b*) sulphate of zinc, commercial, and chemically pure. These articles are largely used in the sizing of cotton goods for the prevention of mildew; (*c*) Sulphide of

zinc, for rubber purposes and as a white pigment. Among the other zinc salts are ferrocyanide, silicate, carbonate, acetate, nitrate, oxide, tannate, bromide, iodide, chromate, phosphate, etc. Probably never before has such a complete set of commercial zinc compounds been shown. The spelter and the zinc ores and minerals which are the natural sources of zinc compounds are also to be seen.

2. Sizing materials for cotton warps and piece goods, also materials used in finishing the same.

3. Recovered indiarubber, substitutes for indiarubber, and chemicals and drugs used in the rubber manufacture. The recovered rubber consists of qualities which range in value from what is almost equal in value to native Para rubber down to qualities which are lower in price than the cheapest native rubber.

The substitutes for rubber are of lower value still. They are (many of them) more lasting in their nature than many forms of real rubber. Both the recovered rubbers and the substitutes are generally used incorporated with new rubbers. The colour of the substitutes varies from dark brown to white, according to their nature and the particular use to which they are put.

The rubber chemicals are used for vulcanising rubber, or colouring it, or giving it body, and consist of such substances as oxide of zinc, sulphide of zinc, sulphide of antimony (red), sulphide of lead, hyposulphite (thiosulphate) of lead, and many of the pigment colours which are used in paints. The rule in using these is that they must not be such as will be affected by combining with the sulphur in the vulcanisation process.

Vesuvian white is a special vulcanising material which Grimshaw Brothers make for use in the manufacture of tennis balls and some other articles. This firm also shows some solvents of rubber—viz., solvent naphtha, chloride of sulphur, bisulphide of carbon, etc., also indiarubber solution or varnish. In addition to the above three series, the following are illustrated :—

H. Grimshaw's patent process for separating and utilising the zinc and iron of galvanisers' waste. The zinc is dissolved by an acid solution of chloride of zinc, which thereby becomes more concentrated, and the iron is left in a pure state. The galvanised waste cannot be smelted, as the zinc makes the iron "short" or "brittle," whereas the iron after it has been treated becomes adapted for working up again.

AN INQUIRY INTO THE EXTENT TO WHICH CALICO PRINTING AND THE TINCTORIAL ARTS HAVE BEEN AFFECTED BY THE INTRODUCTION OF MODERN COLOURS.

(*A Paper read before the British Association, Manchester, 1887.*)

BY CHARLES O'NEILL, F.C.S.

The first of the modern colours was Mr. Perkin's aniline mauve, which was discovered and applied in the year 1856 (August) ; it was two or three years after (April, 1859) that the next modern colour, magenta or fuchsine, made its appearance ; the tide rose slowly in 1860 with purples, blues and violets, gained every year in force and volume, until the flood has now risen to such a height that one who would like to keep up with it stands astonished and dismayed at its extent, and well nigh confounded with the prospect before him. Nor is there any sign that we have got to high-water mark, for month after month chemists and colour manufacturers are patenting new colours or new processes in such numbers that only a specialist of specialists can pretend to follow or appreciate the work that is being done. I do not pretend to be that specialist, but having served my time to dyeing and calico printing before the beginning of the era of modern colours, and been in one way or another engaged in the business ever since, I am enabled to give some sort of account of the differences of the two periods.

The fixing of 1856 as the date when the modern colours came in cannot be seriously objected to, because it is evident that it is the artificial colours introduced in that year, and afterwards for a long time and even now spoken of as aniline colours, which occupy one's thoughts. Just before that date three new colours occupied attention ; these were murexide red, Chinese green or Lo-Kao, and the fast archil purple, but their life was short and their influence *nil* ; a little further back still catechu and ultramarine blue, accompanied by the use of albumen, one a natural and the other an artificial colouring matter, were very welcome additions to the materials of the printer, and still highly valued by both printer and dyer. If the term in the title of the paper had been artificial colours instead of modern colours the claims of Saxony blue or sulphate of indigo, used since 1740, would have to be considered as well as the red and yellow chromates of lead and Prussian blue or royal blue, and some others of great value, which may be considered quite as much made by art as aniline black or the azo reds are made by art ; but the most modern of these were in use long before the date fixed upon, and may be left without further notice.

The relations of the modern colours to the various textile fibres is so very different that it is advisable to treat them separately. In the first place I will take cotton, and afterwards wool and silk, and in cotton give precedence to calico printing. The two most important colouring matters in 1856 were indigo and madder. Neither of these colours could be directly printed on calico. Indigo indeed in the form of China blue, was printed, but it had to be subsequently fixed by a process analogous to dyeing, and it was not an important branch of the indigo styles. All attempts to obtain an extract of madder fit for printing had failed ; it was not until about ten years afterwards that the extract of madder came into the market, and for the first time the printer was enabled to produce by direct application upon the cloth the various colours yielded by madder. Of indigo little need be said. We have seen of late years some advance in the manner of applying indigo, new reducing agents, as the hyposulphite of soda and zinc dust, the actual printing of it by the glucose process of Schlieper and Baum, and the ingenious pigment coloured discharges of Camille Koechlin, but the fundamental indigo styles in which probably nine-tenths of all indigo imported is consumed, remain practically in the same state they were in in 1856. The artificial indigo of Baeyer is a scientific victory, not less remarkable than that of Graebe and Liebermann in the case of artificial alizarin, but it is not an economic success, and has had no visible influence in the trade. The madder styles of 1856 were of great excellence as produced by the best houses, quite as good or better than pure alizarin styles are now ; not that alizarin cannot be made to yield as good work as madder did, but the present conditions of the trade with regard to prices are unfavourable to the highest excellence in that class of prints. In the dyed madder and garancine styles, the designs were practically limited to the four or five colours yielded by madder or garancine, with the help of catechu brown or drab, catechu being the only colouring matter which could be worked in conjunction with the dyes; some years after the date taken, chrome yellow and orange were combined with madder colours, and for a time proved a great relief to printers, permitting a variety in design and colouring not before possible. If it was desired to combine such colours as blue, green, or other shades with madder colours, it could only be done by printing these colours with block after the madder colours had been dyed and finished. All this is changed now, and the calico printer can produce designs of ten, twelve or fourteen colours printed at one time, in which the reds, pinks, purples and chocolates may be alizarin colours, possessing all the stability of the old madder colours. Strictly considered the modern colours cannot be credited with this change, it was actually accomplished as soon as extract of madder was obtainable some two or three years before the discovery of artificial alizarin, but if artificial alizarin had not come up there could not have been the extensive production of many coloured fast cretonne styles which has been a characteristic of the trade for several years past, for extract of madder would always have been a more expensive form of madder and of restricted application. I do not stop to argue the question whether it is proper to consider artificial alizarin a modern colour or not, for the fact of its being identical with something obtainable from madder does not affect its claim to be a new substance. The introduction of this most important and most valuable of the modern colours has had for effect to cheapen the price of the best kind of calico prints: by best I mean those of most durable colours, and used for personal wear. So far it is a boon to purchasers of prints; how far it has benefited calico printers is another question. It would appear that the greater facility of producing passable colours has greatly increased production. The same works and machinery can with this and other modern colours turn out, say 50 to 70 per cent. more printed calico that could have been done in the old madder dyeing days. Even dyeing with artificial alizarin is going out for many styles. It is printed, steamed, passed through an open soaping machine for a few minutes, cleared and finished straight off. This is very different from the old madder dyeing, with first and second dunging, washing, dyeing, two or three soapings and clearing. Increased production without a corresponding increased demand of course leads to a gradual lowering of prices, until profits are cut down to a very low margin indeed. I think it may be held that the colour mixing made easy by the introduction of modern colours has much to do with the unremunerative condition of calico printing. As nearly as I can fix the date it would be in 1852 or 1853 that I saw the newly erected 20-colour printing machine at a now extinct works printing an 18-colour pattern. The same machine is now at another works, and I saw it lately printing a 14-colour design. I ask myself the question, what difference has the 34 years made in the character of the colours and the work, supposing that the colourist was using the best colours available at each time. The reds and pinks then were from cochineal, now they are from alizarin, the blues, greens, myrtles and olives were of the prussiate class, the greys, drabs, browns and chocolates were from the woods—logwood, sapanwood, sumach, etc. It may be said that only the black, which is from logwood, remained essentially the same at both dates, for even in the chocolates and other colours which depended mainly upon wood extracts, there was an admixture of modern colours, while the blues and greens, purples, etc., were unmixed modern colours, with the usual fixing agents. Of course one has to depend upon memory and impressions, for the prints of 34 years ago cannot be now seen in their freshness, but I think there has been no great change in results as far as regards quality of work. There has been a lessening of cost of colour, and a lessening of labour to the colour mixer, and undoubtedly some colours now are brighter than then, but there is not much in that; as to fastness of colour, except as regards the reds there has been no gain, perhaps even a loss.

None of the modern colours except alizarin and its allied blue and orange derivatives can be said to be fast colours upon cotton in the sense that madder or indigo are fast, but at the same time many of them are fast enough for the purposes to which they are applied, and have contributed in calico printing to give a variety in colourings which has no doubt extended the demand for printed goods. In plain dyed calicoes many fancy shades are dyed with these colours and serve well enough for a variety of uses, as linings for garments, hangings, and the like. Improvements in fixing have been introduced of late years, which have materially improved the stability and resistance of many of the colours. Lloyd and Dale's discovery of the utility of tartar emetic, patented in 1861, did not come to be generally used until the patent had expired, but it has been of great service; in combination with tannic acid in the colour, it gives fixity enough to many colours to resist soaping sufficient to brighten and clean the goods.

In the Silk Section of the Royal Jubilee Exhibition there are two exhibits which raise the question of modern colours as to stability. In one case there is a silk patch-work coverlet exhibited of many colours. It was made in 1850, six years before the first of our modern colours came into existence. A written notice informs the visitor that the silks were dyed in the "old fast unfading dyes," and further states that this coverlet "is a striking illustration of a lost Leek industry, a genuine representation of the old fast unfading dyes, which is still practised by us," the exhibitors, "for all purposes for which they may be required." The other exhibit of dyed silks has two sides to it—the silks on one side are said to be "in Eastern unfading dyes, identical in nature with the colours found in the ancient Oriental and Italian needlework, they will bear washing, and they are the same by gaslight as by daylight." On the other side the silks are said to be dyed by modern dyes, and marked for shipping. Of course, the implication in both these notices is that the old dyes are much faster, less liable to fade, and altogether better than the modern dyes; they really contain an assertion that if you want well-dyed silks you must discard the modern and go back to the ancient colours. The idea that all new dyes are bad dyes is one held by numbers of people, who are inclined at the same time to believe that in the old times there were no loose colours. The truth is that with the ancient dyes, as with the modern dyes, there was an abundance of loose, bad dyeing, and it is, perhaps, as well to show that, bad as the moderns may be, their ancestors were not a whit better, and that there were loose colours before aniline. There is a book on calico printing by C. O'Brien, dated 1791. This author had an exalted opinion of the art of calico printing, and condemns in strong language those printers who used only or mainly what he calls chemical colours in printing. He will not give receipts for these colours lest he should increase the number of bad men who used them. He says, in the chapter on colour-making: "By permanent colours every one in the printing line considers those that are not to be removed by soap, sun, nor air; the others are of various kinds, as some withstand washings, but will fly on the air; others will withstand neither, and others only for a little time." Further on he says: "Arbuthnot made some stir with green stalks in light chintz, which soon flew (faded), and no provision being made to supply the vacant parts the cloth then had a truly ludicrous appearance, the flowers seeming scattered here and there without stalks or any other appendage;" and, again, "it is notorious that in many commissioned and other shops, the lowest chemical work, even with such colour as almost, literally speaking, would *shake off*, is warranted and ticketed as 'fast,' and often called chintz." Both in 13th and 23rd of George III. the Legislature interfered with the dyers to stop certain loose colours. Bancroft gives the essence of these Acts, but elsewhere I have read the occasion of their enactment. It was the case of a Government contract for the supply of blue cloth, for navy purposes. It should have been indigo blue, but it was logwood and copper blue. The cloth passed inspection, but as this colour is one of the worst possible, and will not stand 24 hours' sunshine without fading into a dismal brown or buff, the results were disastrous, and the enraged Government threatened to impose the enormous penalty of twenty pounds per piece upon cloth so dyed in the future. Bancroft quotes a curious case of a certain Dr. Richard Williams, who was granted the sum of £2000 in 1773, by Act of Parliament 13 George III. chap. 77, for his discovery of a fast green and yellow dye on cotton yarn and thread. The secret was not to be disclosed for fear the foreigner should reap advantage from it, but Williams supplied the materials to the dyers. It was soon found the colour was no good, as it could not stand light though it would stand soap; yet the inventor was supported by the favourable testimonials of persons to whom he had made presents of pocket-handkerchiefs with borders of yarn woven in which had been dyed with his yellow and green. The colours lasted well enough in pockets, that is in the dark, but faded in the light. These are examples from the literature of the subject, but anyone of sufficiently extended experience knows well enough that loose colours are not peculiar to the modern era. The range of modern colours, just like that of the ancient colours, includes fast and loose, and it mainly depends upon the dyer to select those which are suitable. There are cases in which the dyer has no control, as, for example, in the old safflower pink: it is ordered and must be supplied. There is nothing but safflower which will dye the peculiar safflower pink, and no art or skill can make that colour fast or durable. The same may be said of many light shades dyed with the old dyes, annatto, turmeric, or cudbear, upon either silk or cotton; so with some of the new colours, as eosin, fluorescein, peacock blue, and some others; they are weak colours, and nothing can be done to strengthen them. But to say that the modern colours mostly in use for silk and wool dyeing are characterised by general instability and proneness to fade is not at all true. I think I may go so far as to say that all or nearly all the colours upon the Leek quilted silk could now be dyed with modern colours which would keep their quality as long and as well as those actually on the quilt. If the wholesale condemnation of modern colours that one sometimes hears had any truth in it they must have gone into disuse long ago, for purchasers of dyed goods do not twice purchase a false and deceitful colour. But the opposite is the case, the consumption is increasing; and the respectable dyer knows how far he can use these colours without bringing discredit upon himself.

Whatever may be the true state of the case with regard to cotton, I consider that the introduction of modern colours in the dyeing of silk and wool has been of great service. Between the greater number of these colours and the animal textile fibres there is a direct and powerful attraction which it is the part of the dyer rather to restrain and modify than to assist. For the most part no mordant of any kind is required; simply heating the fibre in a solution of the colouring matter, with, perhaps, addition of a little acid or sulphate of soda, and finally washing, constitutes the whole of the dyeing. Compare cochineal scarlet upon wool with azo red, called fast red or rocceline. They can hardly be distinguished from one another by shade, but the difference of the dyer's work in their production is quite remarkable. In cochineal scarlet the uncertain tin mordant has to be made and applied by prolonged heating with the wool, and then the cochineal dyed upon it, a process requiring much care, and attended with uncertainty in unskilful hands, but the dyeing with azo red is a simple mechanical operation, which can hardly miss at all. This colour threatens to displace cochineal much the same as alizarin has displaced madder. But it is in the fancy shades upon silk and wool that the modern colours have been most useful. Great fastness of colour is not required for these textiles; in a number of cases they are never intended to be washed or treated with acid or alkaline liquids, but the hue of colour should be fresh and the fibre undulled. These conditions the artificial colours fulfil admirably. Some mistakes, no doubt, have been made in employing very fugitive dyes, with loss and annoyance to all concerned, but they can be avoided.

Seeing the comparative ease and facility with which the modern colours can be applied to textiles, it may be asked whether this has not a deteriorating influence upon the foremen dyers and colour mixers, who do not seem to be required to exercise the same care and skill as formerly, and who might be expected therefore to become careless and unprogressive; well, it is true the work seems easier and less responsibility attaches to the foreman, who uses rather than makes colour, but in all reasonably large and active dye-houses, doing a variety of colours, there must be the same watchfulness now as ever there was, for, if it is easy to dye with these colours, it is quite easy also to spoil cloth with them; besides, there is no place of general dyeing that has given up the old dyestuffs, and the dyer must know how to produce blacks, browns, slates, drabs, buffs, etc., which are still made from the more ancient wares.

Except madder and cochineal, it does not appear that the old colouring matters—such as catechu, fustic, logwood, sumach, and peachwood—have been much, if at all, affected by the advent of the modern colours; their consumption has not diminished nor their price gone down. Logwood still remains a main source of black colours upon wool and cotton. Aniline black has been of very great service in calico printing, possessing a stability to which no other black can lay claim, and working very well in some combinations where logwood black would have been very poor. I am thinking of the styles containing much alizarin red and black as well as the chrome orange and aniline black style, both of which had a considerable success. But yet nearly all the blacks in combinations of more than five or six colours are still logwood blacks, but the old iron mordant has been displaced generally by acetate of chromium. I may say, in passing, that the introduction of acetate of chromium as a fixing agent in steam colours, both of the ancient and modern class, has been a conspicuous boon to printing, hardly second to any other material introduced of late years. The dyed blacks and black and whites, called sometimes the mourning style, are yet almost universally produced from logwood; logwood black is soon injured by light and air, and it would be desirable to replace it by aniline black. But there are difficulties in the way, the aniline black, which is dyed in a vat with bichromate of potash, aniline salt, with acids and metallic salts, may be called a precipitate black; it has the disadvantage of rubbing off and soiling white articles. The oxidation black, if that name may be given to the printer's black where the colour is developed through the agency of chlorates and metallic salts, does not rub off and is unexceptionable in hue and stability, but it has the fatal tendency of affecting the fibre, softening and tendering it, unless it be applied with the utmost skill, and, I may say, also the utmost good luck.

Thus I have glanced and touched at some points in textile colouring bearing upon the subject of the theme submitted to me. There is nothing, of course, scientific or even definite in what has been said: it is more properly to be called a speculation, probably a good deal influenced by my personal surroundings or even prejudices; but, in fact, neither I nor any other can at the present time give more than an imperfect estimate as to how the tinctorial arts have been influenced by the modern colours, for we are in the middle of the battle of the colours and can only darkly discern what is going on.

◆◆◆

THE THREE ISOMERIC PYROCRESOLS.

BY DR. W. BOTT,

The Owens College, Manchester.

(Read before the British Association, Manchester, 1887.)

ABOUT five years ago Prof. H. Schwarz, of Graz, in Austria, announced the discovery in coal tar of three new isomeric bodies, which he termed α-, β-, and γ-pyrocresol, and to which he assigned the formula $C_{28}H_{26}O_2$, which later on was corrected to $C_{15}H_{14}O$. A few months before Schwarz's publication appeared, I had been examining a certain by-product obtained during the preparation of phenol and cresol at the chemical works of Messrs. C. Calvert & Co., Bradford, and had succeeded in isolating from it three new substances and prepared several derivatives of them, and I soon recognised Schwarz's pyrocresols to be identical with the bodies I had obtained. I communicated with Prof. Schwarz upon the matter, and we agreed to jointly pursue the further study of the pyrocresols. Unfortunately neither Prof. Schwarz nor I have been able to give very much time to the work until quite lately, so that the investigation is far from complete at present. In a paper prepared by Prof. Schwarz and myself, and read before the Chemical Section of the British Association, at Manchester, in September, we have given a condensed and revised summary of all the facts already known concerning the pyrocresols and part of our new results; the present paper is a more detailed recapitulation of the joint one referred to, with special regard to the more recent results, which have been obtained principally by myself. I may add that, as Prof. Schwarz has now given up working in this direction, I shall continue the work alone, and, in a paper sent to the German Chemical Society, I have reserved to myself the further study of α-, β-, and γ-pyrocresol.

The pyrocresols occur in varying though small
may ties in certain kinds of acid oils or phenols.
wood, re cting such oils with caustic soda a solution is

admixture of mod tracts by acidifying with mineral
greens, purples, etc., w nation leave a pasty residue
with the usual fixing age
somewhat resembling butter in appearance, and containing a considerable percentage of pyrocresols. The yield of this pasty residue seems to vary with the experimental conditions, it apparently increases whenever the walls of the retort become superheated during the distillation. The freshly made, crude product has a dark yellow colour, but on exposure to light and air it turns dark brown or purple. It begins to boil about 180—185°, the distillate upwards from about 325° solidifies on cooling: it is yellow between 330—350°, darker and of a softer consistency above 350°; finally a little charcoal remains in the retort. All the distillates collected at various temperatures are soluble in alcohol and acetic acid with a greenish fluorescence, which becomes less intense upon purification, and is to a certain extent discharged by nascent hydrogen.

In order to prepare the pure substance, the crude product is best pressed between hot plates, so as to effect a partial separation of the α- and β-compound from γ-isomeride, which accumulates in the liquor coming off on pressing. By long protracted crystallisation of the dry residue from boiling ligroïn and benzene the pure α-pyrocresol is first obtained, the β-isomer passing into the mother-liquors along with considerable quantities of the α-compound. The latter can to a certain extent be removed by partial evaporation, and from the residue obtained on complete evaporation of the mother-liquors the β-isomeride is prepared by frequent re-crystallisation from alcohol. The γ-pyrocresol is isolated in a similar manner from the liquor obtained on hot-pressing. It is beyond the scope of this paper to give a more minute description of the mode of preparing the pure pyrocresols; suffice it to add, that the process is a very long and tedious one, and one involving considerable loss of material; but, so far, it has been found impossible to find a better mode of separation. There is one circumstance worthy of mention in connection with the preparation of the pyrocresols, more particularly of α-pyrocresol. When prepared from the freshly made, crude material, the pure product is readily obtained perfectly white; whilst that prepared from material which has been kept for some years, exposed to light and air, shows a pink colour, which cannot be altogether removed by protracted crystallisation nor by boiling with zinc dust and caustic soda. By cautious treatment with chromic trioxide and acetic acid, the colour can, however, be got rid of.

α-*Pyrocresol*, $C_{15}H_{14}O$, is by far the best defined of the three isomers. It can be readily obtained in large shining plates, exhibiting a beautiful bluish fluorescence, and resembling pure anthracene in appearance; also in smaller needles. It is readily soluble in benzene, chloroform, carbon tetrachloride, carbon disulphide, etc.; less so in acetic acid, alcohol, and ether; and quite insoluble in water and alkalis. The latter do not act upon it even under pressure, and it is also not acted upon by acid chlorides like acetyl chloride or solution of phosgene gas, nor by phosphorus trichloride—from all of which it may be re-crystallised without decomposition. It melts at 196°, the solidifying point varying slightly within 4—6° below the melting point. The most striking property of α-pyrocresol, however, is the ease with which it sublimes; so great indeed is this tendency that it makes it impossible to determine the boiling point of α-pyrocresol. Sublimed α-pyrocresol forms beautiful white fluorescent flakes, which are exceedingly light and bulky, so that a very small quantity of pyrocresol suffices for the experiment. The vapour density of α-pyrocresol has been determined, and is in accordance with the formula $C_{15}H_{14}O$.

γ-*Pyrocresol* differs from the α-compound by its much greater solubility in all solvents: the crystals are less well-defined, and invariably needle-shaped. Its melting point lies at 104—105°, and it does not sublime, although it may be volatilised without decomposition, so that its vapour density can be determined. The properties of γ-pyrocresol are altogether less marked than those of the α-product, and the same applies to their respective derivatives.

β-*Pyrocresol*, melting at 124°, stands intermediate between the α- and γ-isomers. It forms needles or laminæ smaller than those of the α-compound, and, like the latter, it can be sublimed, though less readily. Its solubility is about the mean of those of α- and γ-pyrocresol.

OXIDES OF PYROCRESOL: $C_{15}H_{12}O_2$.

Upon oxidation, the pyrocresols take up one atom of oxygen.

α-*Pyrocresol Oxide* melts at 168°, and forms long yellowish needles, turning darker on exposure to light. It is much more soluble in acetic acid and alcohol than pyrocresol itself, and does not sublime readily; although it may be volatilised without change, and admits of a vapour density determination.

γ-*Pyrocresol Oxide* solidifies at 77°, and crystallises in small rhombic plates, which turn red on exposure to light.

β-*Pyrocresol Oxide* is less well defined, its solidifying point lies at 95°.

The oxides above described are prepared by oxidising pyrocresol in acetic acid solution with chromium trioxide, diluting with water, and re-crystallising the precipitated and well-washed oxides from alcohol. They are indifferent bodies, insoluble in water and alkalis. By gentle reduction with HI, at a moderate temperature, they yield pyrocresols again. Upon very energetic reduction, however, they are completely decomposed, yielding products identical with those derived from the pyrocresols themselves, and which will be described later on.

NITRO-COMPOUNDS: $C_{15}H_8(NO_2)_4O_2$.

α-*Tetranitro-pyrocresol Oxide* crystallises from nitrobenzene or glacial acetic acid in small yellowish plates, which, on heating, burn with a flash. It is insoluble in caustic potash, and sparingly soluble in alcohol.

β-*Tetranitro-pyrocresol Oxide* resembles the α-compound, but is more soluble in alcohol.

γ-*Tetranitro-pyrocresol Oxide* forms a granular mass, and has a distinct yellow colour. It is also more soluble in alcohol than the α-derivative.

Nitric acid alone fails to nitrate pyrocresol completely, and chiefly gives rise to oxides. It is therefore best to act upon the oxides at once with nitrating mixture, boil, dilute, wash, and crystallise from hot glacial acetic acid. The product is then washed with absolute alcohol, and dried at 100°.

Upon reduction in alcoholic solution with sodium amalgam, or in acetic acid solution with zinc dust the nitro-oxides yield amido-derivatives, which have not yet been obtained pure, but are being further investigated at this moment.

HALOGEN DERIVATIVES.

When α-pyrocresol is dissolved in chloroform, or carbon tetrachloride, and dry chlorine passed through the boiling solution for a few days, it assumes a very pungent odour, quite different from that of chlorine, and strongly reminding of the smell of acid chlorides; more particularly of phosgene gas. Upon standing this odour disappears, and a white, granular mass separates, which can be re-crystallised from boiling benzene. Upon analysis and re-crystallisation this turned out not to be a uniform product, though crystals were obtained *approximately* answering to the formula $C_{15}H_{12}OCl_2$. By repeated crystallisation we expect before long to obtain a perfectly pure substance. The corresponding β- and γ-compounds have not as yet been prepared.

α-*Dibromo-pyrocresol*, $C_{15}H_{12}Br_2O$, is obtained by mixing acetic acid solutions of pyrocresol and bromine. The precipitate is a mixture of the dibromo-compound with an unstable perbromide, which can be removed by washing with strong alcohol. The dried precipitate is then re-crystallised from boiling benzene, and thus obtained in the form of thick, elongated plates, melting at 215°.

β- and γ-pyrocresol form similar derivatives with bromine.

A number of experiments have been made to exchange the oxygen in pyrocresol for chlorine, as such a substitution would doubtless afford a clue as to the relative position of the oxygen atom. The replacement has been effected in the case of α-pyrocresol; the β- and γ-isomeride have not yet been examined.

Upon gently heating a mixture of α-pyrocresol with phosphorus pentachloride, the mass assumes a dirty green colour, and with chloroform or benzene yields a beautiful, intensely green solution. Upon continued heating in an oil-bath the colour disappears, and if the mixture is then boiled with water, filtered and washed till the filtrate is perfectly free from chlorine, a residue remains containing chlorine. This may be dissolved in chloroform or benzene, but the solutions cannot be made to crystallise, they invariably dry up to a hard, transparent resin resembling shellac.

Since direct treatment with PCl_5 seemed to lead to no satisfactory result, a solution of α-pyrocresol in carbon tetrachloride was mixed with one of PCl_5 in the same solvent, and boiled. A dark yellow powder was precipitated which, however, turned out to be very unstable, readily decomposing with formation of an oil, or resin, so that it could not be re-crystallised. During the above decomposition the intense green colour already referred to is again noticed, and upon washing the precipitate with glacial acetic acid it gradually disappears, yielding a dark green solution. Further experiments will have to show whether this interesting body can be obtained pure and in a crystallised state.

SULPHO DERIVATIVES.

α-Pyrocresol can be sulphonated, though not very readily, and the sodium and barium disulphonates have been prepared. Upon trying to sulphonate the oxide, the latter was found to separate unaltered upon diluting the solution. From this it would appear that the hydrogen atoms in pyrocresol which can be replaced by (SO_3H) are identical with those which upon oxidation are exchanged for oxygen.

REDUCTION OF THE PYROCRESOLS.

As the reduction of oxygenated aromatic compounds has, in many cases, led to the discovery of their mother substance, and thus finally to that of their constitution, it was one of the first things to try and reduce the pyrocresols. Schwarz's experiments to that effect, however, met with no success on account of the great stability of these bodies, and only recently I have been able to reduce α-pyrocresol, and to satisfy myself by preliminary tests that also β- and γ-pyrocresol can be reduced in a similar manner, though the reaction has, so far, been more closely studied in the case of the α-isomer only.

Pure α-pyrocresol was heated with 80 parts of a saturated solution of hydriodic acid in glacial acetic acid, in sealed tubes, to 250—300°. From 1—2grms. of pyrocresol were used at a time, and in some cases aqueous HI saturated at 0° and excess of amorphous phosphorus were used. After heating for two days a copious separation of iodine had taken place, and an oily liquid had separated on the surface of the mixture enclosed in the tubes. The contents of the latter were then neutralised with caustic potash, and distilled with steam, when colourless oil passed over, which was dried by caustic potash, and repeatedly distilled over metallic potassium, so as to free it from traces of iodine which seemed to obstinately adhere to it and caused it to turn violet on heating. Finally, a colourless non-fluorescent oil was obtained, which on fractionation proved to be a mixture of compounds. It began to boil at about 70°, then, excepting one or two short stoppages, the temperature quickly rose, becoming stationary for some time about 275°, the last portions passing over above 300 with slight decomposition. The part boiling at 275° was collected separately and analysed, the following data being obtained :—

(1.) 0·305 substance gave 0·9405 CO_2 + 0·4235 H_2O.
(2.) 0·2205 substance gave 0·6825 CO_2 + 0·3105 H_2O.

I.	II.	Calculated for $C_{15}H_{32}$
C = 84·09	84·46	84·905 p.c.
H = 15·42	15·64	15·095 p.c.
99·51	100·10	100·00

The above analyses agree sufficiently well with the formula $C_{15}H_{32}$, still the result cannot be taken as conclusive with regard to the exact amount of hydrogen, or the number of hydrogen atoms contained in the molecule. Three vapour density determinations were then made by Victor Meyer's method, a diphenylamine bath being employed, and an atmosphere of dry hydrogen being substituted for the one of nitrogen generally used. Upon trying to determine the vapour density in air a dissociation occurred, and a similar, though slight decomposition takes place even in hydrogen, when the diphenylamine bath is replaced by once of anthracene. The following results were obtained :—

I.	II.	III.	
G = 0·1035	0 0820	0·1045	Calculated for $C_{15}H_{32}$: d = 106.
V = 11	8·7	11·8	
K = 10·5	6·5	9·8	
B = 757	763·2	755	
d = 7·69	7·51	7·23	
110·96	108·48	104·32	

mean 107·92

As the small quantity of the reduction product at present at our disposal did not admit of anything like a complete examination, we had to be satisfied with a few preliminary tests. Strong nitric acid or nitrating mixture fail to nitrate the oil ; upon boiling, a kind of resin is formed which is lighter than water. Bromine and strong sulphuric acid have no perceptible action upon the oil. The higher boiling portion distilling at 275° is a perfectly colourless, non-fluorescent, thick oil, having a faint odour reminding of paraffins, and does not solidify even in a freezing mixture.

A considerable time ago we had already tried in vain to reduce α-pyrocresol by means of zinc dust, and Schwarz's experiments seemed to confirm our own negative result. Recently we have, however, repeated the experiment and found that on slowly passing α-pyrocresol over a long layer of heated zinc dust in a current of dry hydrogen or carbonic oxide gas, a yellow, soft mass is formed, having a strong, sweet smell, reminding of anis-seed oil. When distilled with superheated steam it yields an oil, which, as far as we are able to judge at present, is identical with that obtained by reduction in the wet way. The solid residue left upon distilling consists of unaltered α-pyrocresol.

The further investigation of these reductions is being proceeded with.

With regard to the constitution of the pyrocresols we cannot at the present stage of our work offer any definite opinion, still we may safely draw divers conclusions from the results so far obtained, more particularly in the case of α-pyrocresol.

The empirical formula $C_{15}H_{14}O$ is in concordance with the results of the analysis and the vapour density determination, still it cannot be said to have been proved beyond doubt, as a very small difference in the percentage of hydrogen could not possibly be determined by either method. In the worst possible case the formula must, however, be a very close approach to the truth. Taking the formula for granted, the first question arising is that regarding the position of the oxygen atom. Since the absence of an hydroxyl group is evident, from the fact that neither alkalis, nor acid chlorides, nor phosphorus trichloride have any action upon pyrocresol, we must assume the oxygen to be directly linked to carbon, and this again admits of two possibilities. We may suppose the oxygen to be contained in a carbonyl group C = O, which would impart to pyrocresol the general character of a ketone. Schwarz, in fact, at one time believed α-pyrocresol to be a ditolyl ketone $C_7H_7.CO.C_7H_7$, and although the properties of dibenzyl and ditolyl ketones as described by Fischer and Weiler (*Ber.* vii. 1183) and E. Hepp (*Ber.* vii. 1439) are different from those of α-pyrocresol, still it might have been an isomeric ketone. In order to settle this question we tried to combine α-pyrocresol with hydroxylamine and phenylhydrazine but without success, neither α-pyrocresol nor the β- and γ-isomers act upon hydroxylamine or Fischer's reagent, however one may vary the experimental conditions. The absence of a carbonyl group is made still more probable by the fact that no acid oxidation product of α-pyrocresol could be obtained and no disubstituted methane—like ditolylmethane—seems to be formed upon reduction. We can at the present time epitomise our views in saying that we believe α-pyrocresol and its isomerides to be anhydrides like diphenyl ether, consisting of two chains held together by oxygen, thus :

$$\begin{matrix} CxHxC & \\ & O \\ CyHyC & \end{matrix}$$

As to the structure of the two chains and the relative position of the oxygen atom connecting them, we cannot express any decisive views until we shall have more closely studied the reduction products and the chloride obtained with PCl_5. As the reduction of α-pyrocresol gives rise to the formation of a mixture and one of the constituents of this mixture contains the original number of carbon atoms, it is possible that the other products have resulted from the reduction of the separated chains, and that this dissociation has taken place at the point where the oxygen atom is attached, in which case the reaction would be directly indicative of the relative position of this oxygen atom. The chemical nature of the reduction products remains to be ascertained. The properties of the high boiling hydrocarbon are different from those of known compounds having a similar composition—viz., pentadecane $C_{15}H_{32}$, quindecon $C_{15}H_{26}$, benylene $C_{15}H_{28}$, triamylene $C_{15}H_{30}$, etc., etc. ; it may possibly not be a paraffin, but belong to the class of hydrocarbons which Markownikow and others have termed "naphthenes," though this is at present a mere speculation. There is no doubt that the continued investigation of the reduction products will soon throw light upon the matter, and ultimately upon the structure of the pyrocresols.

In conclusion, we may add that a number of experiments—some on a large scale—have been made with a view of obtaining an insight into the origin and mode of formation of pyrocresols in coal tar, which would furnish a valuable clue to their synthesis. Some of the results have already been made known at the recent meeting of the British Association, but as their discussion is beyond the scope of this report, we reserve these and subsequent results for a separate paper.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

Improvements in Apparatus for Preventing Corrosion of, Preventing Incrustation in or Facilitating the Removal of Incrustation from Steam and other Boilers. S. Hoyle, Accrington. Eng. Pat. 11,025, August 30, 1886. 8d.

WHEN zinc is used as an electrode in the interior of a steam boiler for the purpose set forth, the patentee proposes to use it in a cylindrical form mounted upon a cup-shaped brass tray pivoted on a stud in the interior of the boiler, at such a point that the motion of the water causes an oscillation, thus keeping the point of contact clean and bright.—C. C. H.

Improvements in Filters for Filtering Water for Manufacturing Purposes. C. Hird, Huddersfield. Eng. Pat. 11,304, Sept. 2, 1886. 8d.

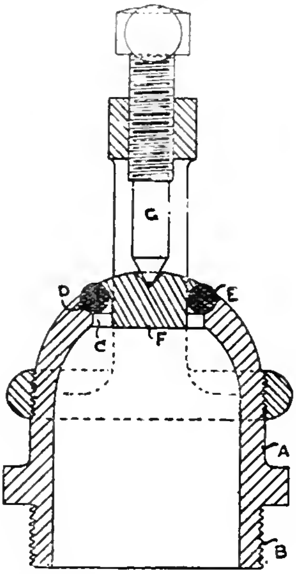
A SQUARE or oblong tank is provided with perforated sloping shelves one above the other, upon each of which is a bed of filtering material kept in place by means of a perforated corrugated plate. The water is admitted at the bottom of the tank and on to a perforated plate, which catches and retains the coarser impurities ; it ascends through the filtering beds and flows off at the top of the tank. Wash-out and drain cocks are provided for removing the sediment which accumulates between the filtering beds.—C. C. H.

A Cock for Charging Air and Liquor combined into Stills and other Vessels. J. Harvey, Port Dundas. Eng. Pat. 5358, April 13, 1887. 11d.

THE object of the improved cock is to prevent the collapse of a still, into which liquor is being charged, owing to the formation of a partial vacuum due to the condensation of steam or vapour within the still. It consists of a cock with two passages or pipes at right angles to and one above the other ; the lower pipe is connected with the bottom of the still and serves for the admission of the liquor. One branch of the upper pipe is open to the air and the other connected to the upper port of the still. The plug of the cock is hollow, but the upper and lower portions are separated by a cast diaphragm. It follows that when the lower port is so placed as to admit liquor to the still, the upper port is open to the air and the upper part of the still.—C. C. H.

Improvements in Fusible Plugs for Steam Boilers, Feed Water Heaters and other Appliances connected with Steam Boilers. W. Williams, Peckham. Eng. Pat. 3364, March 4, 1887. 8d.

THE improved fusible plug is made as shown in the drawing attached : A is the gun-metal body screwed into the flue of the boiler at B from the water side of the boiler. F is the loose or falling plug forced by the pressure screw G upon the ring E of soft fusible metal which rests upon the seating D ; the action of such a plug is well understood.—C. C. H.



An Improved Screen-bottom for Bone Charcoal Washing and Filter Tanks. A. Van Kroger, San Francisco, U.S.A. Eng. Pat. 9909, July 14, 1887.

THE screen-bottom forming the lower part of the base of the charcoal washing tank used in sugar refineries is formed by a number of frames ; each frame has solid sides grooved at the bottom edge for a jointing material, and the top and bottom of the frame is formed of perforated plate. The space between the two plates is packed with sand, fine gravel or other suitable material. The fine char which would otherwise be carried away, is retained during the washing.—C. C. H.

A Combined Evaporating and Calcining Furnace. F. Siemens, London. Eng. Pat. 13,789, Oct. 27, 1886. 8d.

THE improved furnace is shown in the accompanying drawings ; Fig. 1 is a longitudinal section, Fig. 2 a sectional plan. Gas from a producer enters the furnace at G, meets with air entering the flue I and the flame generated passes into the interior of the furnace at E.

---

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows :—

If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
,, 1s. 6d., ,, ,, 2s. 4d...	1½d.
,, 2s. 4d., ,, ,, 3s. 4d...	2d.

A portion of the flame passes over the hearth A, and the remainder emerges therefrom through the passages D, circulates round the evaporating pan C and back to the body of the furnace through D' ; the consumed gases leave the furnace at MM. If a stronger heat is required in the pan C, bricks covering a number of openings *b b* are removed, admitting a larger portion of the flame underneath the pan C. The dried material removed from the pan is fed on to the hearth of the furnace through passages K K leading from the upper surface of the setting of the pan to the hearth A, from which, after calcination, it is removed through the doors L L.

II.—FUEL, GAS AND LIGHT.

The Influence of the Composition of Petroleum and of the Salts contained therein on its Illuminating Power. E. Alftan. Zap. Imp. Russk. Techn. Obszcz. 1887, **21**, 107.

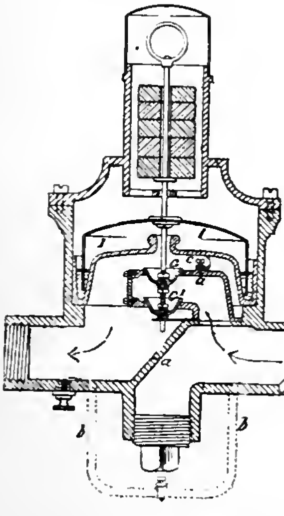
While petroleum is now commonly tested in regard to alkalinity or acidity, the influence of the ingredients on the luminosity of the flame has been neglected. The author has distilled an ordinary commercial sample of Nobel's petroleum into three fractions :—(1) with sp. gr. of 0·7647 and boiling point under 150° ; (2) with sp. gr. of 0·8287 (normal) and boiling point between 150° and 270° ; and (3) with sp. gr. of 0·867 and boiling point over 270°. The two latter were then mixed in various proportions and sufficient of the light distillate was added in each case to bring the product down to the normal sp. gr. of 0·8287. These mixtures were then burnt severally in a Kuhmberg lamp and the decrease in illuminating power determined photometrically, always after known periods of time. With mixtures containing 20 per cent. of heavy hydrocarbons the decrease in luminosity after eight to nine hours amounted to 7·3—9·5 per cent., with those containing 20—40 per cent. the decrease was 22—48 per cent., and with one made up with 50 per cent. of No. 3 the loss of light was 56·7 per cent. In the last-named mixtures the wick was more sooty than in the first. The author ascribes the diminished luminosity to the slow rise of the heavy oil in the wicks. In regard to the presence of salts, the bases most frequently occurring are iron oxide, lime and magnesia. A sample of petroleum insufficiently neutralised with soda, either gives an acid reaction, when it becomes yellow on standing in iron vessels owing to the solution of iron, or else it contains organic salts, in which case it burns so badly that the flame may even become extinguished after one or two hours. It is found that the presence of 0·1grm. of iron salts per 1000grms. of petroleum is not prejudicial, and this is an exceptionally high percentage ; but even 0·02 per 1000 of lime or magnesia salts may suffice to reduce the luminosity by 30—40 per cent. after eight hours, and 0·1 of lime per 1000 lowers it 85·5 per cent., while the same proportion of magnesia compounds reduces it 94 per cent. This remarkable difference in the effect of iron oxide and of these bases is traced by the author to the fritting together of the latter in the wick, with consequent obstruction to the passage of the petroleum, whilst the iron oxide remains pulverulent at the summit of the wick or falls away as a powder. It is especially to be observed that no lime or magnesia have been found in samples having an acid reaction ; by creating, however, a demand for alkaline petroleum it is quite conceivable that a product containing these objectionable impurities might find its way into the market.—W. G. M.

Improvements in the Manufacture of Gas from Mineral Oil and in Apparatus therefor and connected therewith. J. M. Turnbull, Edinburgh. Eng. Pat. 11,833, Sept. 17, 1886. 8d.

REFINED or "medium" oil is admitted to the interior of an externally heated retort. The cross section of the retort is such that a ridge running down the centre leaves a hollow on each side, which may be filled with open refractory material in order to expose a greater surface, and so assist the gasification. The gas thus generated passes through a cooler and washer of ordinary form to the gasholder or bellows, which is made like a photographic camera expanding vertically upwards in a suitable frame. The topboard of the gasholder, when this latter is full, comes in contact with a weight at the end of a rod, and, raising this, effects the shutting of a tap which stops the oil supply to the retort. The supply is thus automatically regulated.—A. R. D.

Means for Indicating Escape of Gas: Specially Applicable for Buildings and Domestic Use. J. Stott, London. Eng. Pat. 13,577, Oct. 23, 1886. 8d.

THIS invention is intended to be applied to an apparatus such as that described in Eng. Pat. 10,348 of 1886, and is illustrated in the accompanying figure. A hole *a* in some convenient part of the apparatus, or a by-pass *b*, allows the escape of a minute quantity of gas even when the valves G, G_1, are seated. Thus if the gas, after having been turned off at the meter, be turned on again, sufficient will escape at the open burners to indicate the state of affairs, but not enough to do harm. When the burner taps are closed, this gas will accumulate under the float I, and, causing the stop valves, G, G^1, to rise, allow the main supply to pass through and be lighted in the usual manner. The hole *a* is fitted with a regulating screw *c* to determine the size of the passage.—A. R. D.



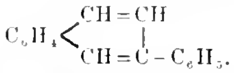
Apparatus for Inducing Complete Combustion of Mineral Oil, Gases or Smoke, to be used for Heating or Lighting Purposes. G. T. Chinnery, Gateshead. Eng. Pat. 13,752, Oct. 27, 1886. 6d.

THE oil is incompletely burned in a vessel provided with a cover and fitted with a steam-coil to warm the oil if necessary. Inside the vessel is also placed an ejector so disposed as to draw off the vapours and gases formed by the incomplete combustion going on in the vessel, and discharge them by an opening in the cover. The ejector is fed with compressed air, steam, or air and steam together. This mingling with the oil gases forms a highly inflammable mixture, which burns with a white light and great heat.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Constitution of the Hydrocarbon $C_{16}H_{12}$ from Styrolene Alcohol—Phenylnaphthalene. T. Zinke. Annalen, **240**, 137—146.

IT has already been shown that the constitution of the hydrocarbon $C_{16}H_{12}$ obtained from styrolene alcohol and phenylacetaldehyde is represented by the formula $C_6H_5.C_4H_2.C_6H_5$, it being assumed that the condensation takes place in two stages as in the case of the condensation of acetaldehyde to crotonic aldehyde. Further researches on the constitution of this hydrocarbon tend to show that it is β-phenylnaphthalene, the reaction which gives rise to its formation probably including the following phases :—(1.) Two molecules of the phenylacetaldehyde unite to form 1 molecule of an aldole having the formula : — $C_6H_5.CH_2.CH(OH).CH(COH)C_6H_5$. (2.) This aldole then parts with 1 molecule of water, being resolved into *diphenylisocrotonic aldehyde* $C_6H_5.CH:CH.CH(COH)C_6H_5$. (3.) The latter also loses 1 molecule of water, of which one hydrogen atom is absorbed by a phenyl group, by which means the naphthalene ring is formed, thus :—



$$C_6H_4\left<\begin{array}{l}CH = CH\\ \quad\quad\;\;|\\ CH = C - C_6H_5.\end{array}\right.$$

β-phenylnaphthalene. The formation of the above aldole may be explained also by assuming that a phenyl group takes part in the condensation, in which case the following intermediate product is obtained :—$C_6H_5.CH_2CH(OH).C_6H_4.CH(COH)$. The reaction which gives rise to the formation of this compound corresponds with von Pechmann's synthesis of coumarin. This product then loses 2 molecules of water in two phases, an aldehyde being first formed, which is subsequently converted into the hydrocarbon thus :—$C_6H_5.CH:CH.C_6H_4.CH_2.COH$ and

$$C_6H_5.\overset{\llcorner}{C}:CH.C_6H_4.CH:\overset{\lrcorner}{C}H.$$

β-phenylnaphthalene. The author has prepared β-phenylnaphthoquinone, the hydroxyquinone and the amido-methylamine and aniline derivatives. In confirmation of the view that this hydrocarbon is phenylnaphthalene it is stated that on oxidation the theoretical amount of benzoic acid is obtained. Moreover, on oxidation with potassium permanganate the hydroxyquinone forms phthalic anhydride and an acid of the formula $C_6H_4CO(COOH)_2$, together with benzoic acid, a circumstance which affords additional proof to the correctness of the author's opinion regarding the constitution of the hydrocarbon. Unsuccessful attempts were made to prepare this compound by synthesis. The author also failed in his endeavours to obtain diphenylisocrotonic acid from phenylacetaldehyde and sodium phenylacetate.—D. B.

Pyrene. E. Bamberger and M. Philip. Annalen, **240**, 147—192.

NEARLY all the contents of this paper, which gives a complete resumé of the researches on pyrene, have been previously published. After some historical references, the authors allude to the numerous investigations on the constitution of pyrene, and point out that it has been established beyond doubt that pyrene represents a combination of a naphthalene nucleus with two benzene nuclei. In the experimental portion of the paper the authors describe in detail the preparation and properties of pyrene and a large number of its derivatives. The raw material from which the hydrocarbon was extracted was the by-product formed in the condensation chambers when mercury ores are smelted (in Idria). This product, called "stuppfett," has been investigated by Goldschmidt and Schmidt (*Monatsh. Chem.* 1881, 1), who isolated about twelve different substances therefrom, among which pyrene occupied the second place as regards yield. The extraction of pyrene from this material was effected by the authors by digesting the mass with alcohol on a water-bath, decanting the alcoholic solution and collecting and pressing the residue. The latter was then extracted with boiling alcohol, in which it all dissolved with the exception of a small quantity of inorganic matter. On cooling, a yellowish brown crystalline powder separated, which was collected on a filter and pressed. From this the pyrene was obtained by fractional crystallisation of its picrate from alcohol, in which medium it is the least soluble. The picrate was then decomposed with ammonia and the hydrocarbon recrystallised from alcohol.—D. B.

Action of Sulphuric Acid on Ozokerite. R. Zaloziecki. Dingl. Polyt. J. **265**, 178—184.

It is known that the yield of ceresin is largely affected by the purification of ozokerite with sulphuric acid, from 15 to 30 per cent. being lost during this operation. The author has attempted to determine the conditions under which the most favourable results are obtained. He finds that between 160° and 200° the yield is approximately the same, being, if anything, in favour of the higher temperature. This apparently anomalous result is explained by the fact that on increasing the temperature the sulphonic compounds originally produced are decomposed with regeneration of sulphurous anhydride and hydrocarbons. Two reactions appear to govern the action of sulphurous anhydride at high temperatures, the one occasioning the decomposition of the organic matter with separation of carbon and formation of water and sulphurous anhydride, and the other effecting the splitting up of the sulphonic acids with reproduction of certain constituents. The former constitutes a source of loss; the latter one of gain. It is stated in conclusion that the residual waste acid may be employed with advantage for the purification of a fresh portion of ozokerite, inasmuch as it contains a considerable quantity of free sulphuric acid; and the heavy, spongy precipitate facilitates the clarification of the mass by absorbing the separated particles and precipitating them.—D. B.

Amount of Nitrogen in Different Coals and Production of Ammonia therefrom. E. Schilling. Dingl. Polyt. J. **265**, 218—222.

The specimens of coal examined represent all the best known types found in different parts of Germany and used for gas making. The following results were obtained:—The amount of nitrogen in the coals ranged from 1 to 1·5 per cent., whilst the coke which they produced contained from 1·2 to 1·4 per cent. The coke from cannel coal, however, contained less nitrogen. The amount of nitrogen present in coal diminishes with an increase in the percentage of oxygen. The production of ammonia varied considerably, ranging from 0·094 to 0·284kilo. per 100kilos. of coal. It rises and falls with the total nitrogen present in the coal. The yield of ammonia from 100 parts of total nitrogen gave a mean of 14 per cent., the maximum result being 20 per cent. The addition of 2·5 per cent. of lime to coal influences the production of ammonia in various ways, some specimens being unaffected whilst others exhibit a considerable increase in the yield of ammonia.—D. B.

Conversion of Higher Homologues of Phenol into Primary and Secondary Amines. R. Lloyd. Ber. **20**, 1254—1265.

Isobutylphenol, isamylphenol, thymol and carvacrol, when heated to 320—350° with zinc bromide ammonia and ammonium bromide, or the corresponding chlorine compounds, give the corresponding primary and secondary amines. Carbonaceous matter is also formed. Carvacrol gives a yield or 70 per cent. of the amine; the other phenols vary between 45 and 60 per cent. On the whole the homologues of phenol appear less capable of reacting than phenol itself.

Carvacrylamine is an almost colourless oil, which solidifies in a freezing mixture and boils at 241—242°. Diphenisobutylamine $(C_4H_9C_6H_4)_2NH$, diphenisamylamine $(C_5H_{11}.C_6H_4)_2NH$, dithymyl- and dicarvacrylamine $(C_3H_7CH_3.C_6H_3)_2NH$, are only liquids boiling above 300°, which, on distillation, are colourless, but rapidly darken. All these amines yield characteristic platinum double salts.—J. B. C.

Substituted Naphthylene Diamines. J. Annaheim. Ber. **20**, 1371—1374.

The preparation of these compounds is based upon the well-known reaction of Merz and Weith for converting phenols into amines. If dioxynaphthalenes be substituted for phenol, naphthylene diamines are obtained. In this way dioxynaphthalene condenses with aniline and aniline hydrochloride to form diphenylnaphthylenediamine $C_{10}H_6:(C_6H_5.NH)_2$. The action takes place at 145—160°, and no dehydrating agent is necessary. It is a solid body, crystallising in brilliant plates. Similar compounds are obtained with para- and orthotoluidine and xylidine, etc.—J. B. C.

Ethereal Salts of Benzoyl Sulphimide and of o-Sulphamido-benzoic Acid. C. Fahlberg and R. List. Ber. **20**, 1596—1604.

Benzoyl sulphimide, when neutralised with caustic soda or sodium carbonate and evaporated, yields a sodium salt. The dry salt, heated with ethyl iodide to 230°, yields the ethyl ether of the imide. It has the formula $C_9H_9SO_3N$. This compound is decomposed with hot HCl, and gives *o*-sulphobenzoic acid and ethylamine, just as the imide yields sulphobenzoic acid and ammonia. This compound must, therefore, have the formula—

$$C_6H_4 < \begin{matrix} CO \\ SO_2 \end{matrix} > NC_2H_5.$$

Heated with alcoholic potash, a compound of the formula $COOK.C_6H_4.SO_2.NKC_2H_5$ is obtained, and on acidifying the aqueous solution the free acid $COOH.C_6H_4.SO_2NKC_2H_5$ is precipitated in the form of an oil, which solidifies on standing. The ethereal salt of *o*-sulphamidobenzoic acid is prepared by passing HCl gas into the alcoholic solution of benzoyl sulphimide. It has the formula $SO_2.NH_2.C_6H_4.CO_2C_2H_5$, and is isomeric with *o*-ethylamidosulphobenzoate. Heated with potash, not the free acid, but the potassium salt of the sulphimide is obtained. An analogous compound to the above is obtained by passing HCl gas into an alcoholic solution of sulphamidobenzoyl sulphimide.

As *o*-sulphamidobenzoic acid cannot be obtained from its ethereal salt, the authors attempted to prepare the ethereal salt from the acid. Ortho-toluenesulphamide, on oxidation with K_3FeCy_6 yields the acid. On passing HCl gas through the alcoholic solution, the sulphimido compound is obtained, but on treating the sodium salt of *o*-sulphamidobenzoic acid with ethyl iodide the ethereal salt is formed.

Its identity with that from benzoyl sulphimide was further confirmed by comparison of its characteristic decomposition products.

1. The sulphimides of aromatic hydrocarbons are, therefore, the anhydrides of the corresponding *o*-sulphamidocarboxylic acids. Both compounds are strong acids, and yield ethereal and metallic salts.
2. The salts of *o*-sulphamidocarboxylic acids give sulphimides on heating, as also the free acid and ethereal salts.
3. The alkaline salts yield, with haloid ethers, ethereal salts, in which the H of the imido group is replaced by the alcohol radical.
4. The ethereal salts give on saponification with alcoholic potash the ethereal salt of *o*-sulphamidocarboxylic acid, isomeric with the other ethereal salt of the same acid.
5. With HCl the ethers of the sulphimides yield alcohol bases and sulphonic acids.
6. The sulphimides are readily converted into the ethers of the *o*-sulphamidocarboxylic acid.—J. B. C.

By-products in the Manufacture of Thiophen. V. Meyer and K. Neure. Ber. **20**, 1756—1758.

THE higher boiling liquid remaining after distilling off the thiophen (prepared by Volhard and Erdmann's method), solidifies on cooling and consists of thiosuccinic anhydride and succinic anhydride. In addition to the solid constituents an oil remains which distils with steam and consists of a portion soluble in alkali and another insoluble in alkali. The soluble portion is thienylmercaptan $C_4SH_3.SH$. The solution of the mercaptan in concentrated alcoholic ammonia yields, on spontaneous evaporation, thienyldisulphide $C_4SH_2.S.S.C_4SH_2$. The portion insoluble in alkali was too small to be identified but contains probably thienylsulphide. —J. B. C.

Preparation of Anthranol and Dianthryl. C. Liebermann and A. Gimbel. Ber. **20**, 1854—1855.

Anthranol.—10grms. of anthraquinone in 4—500grms. of glacial acetic acid are boiled, and 25grms. of granulated tin added. The yellow liquid changes to brown, especially on addition of about 10cc. of concentrated HCl, but regains its original colour. Small quantities of HCl are added from time to time, as long as the solution darkens on addition of the acid. After about a quarter of an hour the process is complete. The end of the reaction may be recognised by the solution remaining clear on cooling. The anthranol is precipitated by pouring into water containing HCl and may be obtained pure by one recrystallisation from glacial acetic acid.

Dianthryl.—Anthraquinone is mixed into a thin paste with boiling glacial acetic acid, 40grms. of tin in 2—3 portions are added to every 10grms. of anthraquinone, and half the quantity of concentrated HCl to that of the acetic acid used. The latter is added in two portions. The mass is kept boiling for an hour. It becomes grey and is then decanted from unattacked tin on to a filter and washed with water. The substance is best crystallised from toluene.—J. B. C.

IV.—COLOURING MATTERS AND DYES.

Manufacture of the Ethylether of a New Acid. O. Imray, London. From the Society of Chemical Industry in Basle, Switzerland. Eng. Pat. 14,617, Nov. 11, 1886. 4d.

FOR the production of this new substance, which has the formula $C_{14}H_{24}N_2O_4$, 1·5 parts of ethylenediamine are heated on a water bath with 5 parts of acetylacetic ether. On cooling, a crystalline mass separates, which is collected on a filter and recrystallised from alcohol. The new compound is thus obtained in the form of needles or prisms, melting at 126° C. It is insoluble in water, sparingly soluble in petroleum spirit but dissolves readily in alcohol, ether, acetic ether, glacial acetic acid, chloroform, benzene, toluene and dilute acids.—D. B.

On the Production and Applications of Aniline Chromates. C. Girard and L. L'Hote. Compt. Rend. **105**, 284.

GRAWITZ, in a communication laid before the Academy (*Compt. Rend.*, 1887, 182) in reference to the authors' researches on a crystalline aniline chromate, pointed out that aniline chromates formed by double decomposition, had been crystallised by Persoz in 1872 (*Bull. Soc. Ind. Mul.*); that Zurcher in 1876 had obtained fine yellow crystals of the salt by the action of potassium bichromate on a slightly acid solution of aniline hydrochloride; and that he himself, in a patent dated Nov. 3, 1874, had recommended the use of this chromate in the manufacture of various dyes. To all this the authors reply that aniline chromates are constantly being produced, but that no one had previously isolated and examined the bichromate described by them, by the aid of which they had produced a whole series of dyes, and hoped also to obtain an aniline black. Contrary to Grawitz's assertions, it could be isolated in a pure condition only by working with an acid solution of an aniline salt.—W. G. M.

On Triphenylmethane Derivates. E. Kock. Ber. **20**, 1562—1566.

THE action of benzaldehyde on aromatic bases to form triphenylmethane derivatives have been studied by Ullmann and others. The author adopts the same method, employing substituted aldehydes and substituted bases. Thus he finds that although *m*-toluidine does not react readily with benzaldehyde, dimethyl-*m*-toluidine combines with *p*-nitrobenzaldehyde to form tetramethylditolylnitrophenylmethane $C_6H_4NO_2.CH.(C_6H_3.CH_3.N(CH_3)_2)_2$. Similar condensation products are produced with dimethyl-*m*-chloraniline and *p*-nitrobenzaldehyde and *m*-anisidine and *p*-nitrobenzaldehyde. It appears, therefore, that although the meta substituted aromatic bases form with difficulty triphenylmethane derivatives, the reaction proceeds readily on converting the base into a tertiary amine. It is also interesting to note that the leuco-bases with two meta-positions in one benzene nucleus do not yield colouring matters on oxidation, which is not the case with the ortho- and para-compounds. With anisidine, however, the meta-position does not produce this effect.—J. B. C.

Formation of Haloid substituted Amido-Compounds by the Reduction of Nitro-hydrocarbons. E. Kock. Ber. **20**, 1567.

THE author has prepared a chlorotoluidine by the action of tin and HCl upon *m*-nitrotoluene. This is identical with the compound prepared by Hönig and Goldschmidt, by nitrating *o*-chlorotoluene and then reducing the nitro compound thus obtained. The substance is therefore *o*-chloro-*m*-toluidine. It combines with phosgene to form di-*o*-chloro-*m*-tolylurea and gives a thio-urea of the formula $CS(NH.C_6H_3Cl.CH_3)_2$.—J. B. C.

A Tabular Survey of the Artificial Organic Colouring Matters. G. Schultz and P. Julius. Chem. Ind. **10**, 295—305.

THE first column of the table contains the commercial names, and the letters in square brackets denote which firm uses the particular names :—[A] The Berlin Actiengesellschaft für Anilinfabrikation. [B] Badische Anilin- and Soda-Fabrik, Ludwigshafen a/Rh. [Bi] Actiengesellschaft für Chem. Industrie (late Bindschedler and Busch), Basel. [By] Farbenfabriken, formerly F. Bayer & Co., Elberfeld. [C] Leopold Cassella & Co., Frankfurt a/M. [D] Dahl & Co., Barmen. [DH] L. Durand & Huguenin, Basel. [K] Kalle & Co., Biebrich a/Rh. [L] A Leonhardt & Co., Mühlheim, Hesse. [M] Farbwerke, formerly Meister, Lucius & Brüning, Hoechst a/M. [Mo] P. Monnet & Cie, La Plaine, Geneva. [O] K. Oehler, Offenbach a/M. [P] Societé Anonyme des Matières Colorantes, et Produits Chimiques de St. Denis, Paris. [Sch] The Schöllkopf Aniline and Chemical Co., Buffalo, U.S.A. [V] Verein Chemische Fabriken, Mannheim. The second column contains the scientific names; the third, the constructional formulæ; the fourth, a concise notice of the methods of formation; the fifth, the years of discovery; the sixth, the names of the discoverers, number of the German patent and reference to the literature on the subject; and the last column contains the characteristic reactions. In the fourth column, under *β-naphthylaminemonosulphonic acid* Br, is understood the acid patented by Messrs. F. Brönner & Co., German patent No. 22,547; *β-naphthylaminemonosulphonic acid* D, that obtained by Dahl, German patents Nos. 29,084, 32,271, 32,276; *β-naphthylamine- δ -monosulphonic acid*, of F. Bayer & Co.'s German patent 39,925; *α-naphtholmonosulphonic acid* NW, that obtained by Nevile and Winther from naphthionic acid; *α-naphtholmonosulphonic acid* C, Cleve's acid; *α-naphtholdisulphonic acid* Sch, that patented by the Schöllkopf Aniline Co., No. 40,571; *β-naphtholmonosulphonic acid* B, patented by Bayer, No. 18,027; *β-naphtholmonosulphonic acid* S, Schaeffer's acid; and *β-naphtholdisulphonic acid* R and G, those of the German patent 3229.

I.—NITROSO-COLOURS.

No.	Commercial Name.	Scientific Name.	Constitutional Formula.	Formation.	Date of Discovery.	Number of German Patents, References, etc.	Reactions, etc.
1	Dinitrosoresorcein. Solid green.	Dinitrosoresorcinol.	$C_6H_2\left\{\left(\begin{array}{c}O\\ \mid\\ NOH\end{array}\right)_2\right.$	Action of nitrous acid upon resorcinol.	1875	FITZ. *Ber.* **8**, 631.	A greyish brown powder, easily soluble in hot water, with difficulty in cold; soluble in dilute caustic soda. Deflagrates slightly when heated.
2	Naphthol green B. [C.]	Sodium-ferrous-salt of nitroso-beta-naphthol-monosulphonic acid.	$C_{10}H_5\left\{\begin{array}{lr}\multicolumn{2}{c}{SO_3NaNaO_3S}\\ O & O\\ \mid & \mid\\ \multicolumn{2}{c}{NO-Fe-ON}\end{array}\right\}C_{10}H_5$	Action of nitrous acid upon beta-naphtholmonosulphonic acid S and formation of the sodium-ferrous salt.	1883	OTTO HOFFMANN, *Ber.* **18**, 46. Frankfurter Anilinfarben-fabrik, GANS & Co. Patent 28,065, 19 Jan., 1884; 28,901, 16 March, 1884.	A dark green powder; leaves when ignited on platinum a residue of iron sulphide. Soluble in water with yellowish green colouration. HCl—no change. NaOH—colour becomes blue-green. Concentrated H_2SO_4 yellow-brown solution, becomes yellow on dilution with water and gives iron reaction with both ferri and ferro-cyanides.

II.—NITRO-COLOURS.

No.	Commercial Name.	Scientific Name.	Constitutional Formula.	Formation.	Date of Discovery.	Number of German Patents, References, etc.	Reactions, etc.
3	Picric acid, or Welter's bitter.	Symmetrical trinitrophenol.	$C_6H_2\begin{cases}(1)\ OH\\(2)\ NO_2\\(4)\ NO_2\\(6)\ NO_2\end{cases}$	Action of nitric acid on phenol or phenol sulphonic acid.	1771 1842 1869	WOULFE (from indigo). LAURENT (from phenol). *Annalen*, **43**, 208. R. SCHMITT and L. GLUTZ. *Ber.* **2**, 52.	Pale yellow crystals, soluble with difficulty in cold water, easily soluble in hot water, alcohol, benzene, etc.; melts at 122·5°. Tastes bitter. Boiled with potassium cyanide forms a brown solution.
4	Victoria yellow. Jaune Anglais. Victoria orange. Safron substitute. Aniline orange.	Mixture of the alkali salts of dinitro-ortho- and para-cresol.	$C_6H_2.OK.CH_3.(NO_2)_2.$ $[OK:CH_3=1:2$ or $1:4]$.	Action of nitric acid on a variable mixture of *o*- and *p*-cresolsulphonic acid.	1869	MITTENTZWEY.	A red-yellow powder; potash salt deflagrates; ammonia salt burns off. Soluble in water with orange-yellow colour. HCl—white precipitate of dinitro-cresol. NaOH—no change, but ammonia given off from the ammonia salt. Concentrated H_2SO_4—pale yellow solution.
5	Flavaurin.	Ammonia salt of di-nitrophenol-*p*-sulphonic acid.	$C_6H_2.ONH_4.(NO_2)_2SO_3NH_4.$ $[OH:NO_2:NO_2SO_3H=1:2:6:4]$.	Action of nitric acid on mononitrophenol-*p*-sulphonic acid.	1874	JUL. POST. *Ber.* **7**, 1323. Leipziger Anilin Fabrik. BEYER & KEGEL. Patent 27,271 (lapsed).	A yellowish-red powder; rises like a "Pharaoh's serpent" when heated. Yellow solution in water. HCl—wine-red coloration NaOH—ammonia given off and solution darkened, which zinc dust turns brown, and decolorises on boiling; air restores the brown colour. Concentrated H_2SO_4—wine-red solution, colourless on dilution.
6	Phenyl brown. Phénicienne. Phenicin. Rothein (No longer in use)			Action of nitric acid on crude phenol.	1863	J. ROTH. *Bull. Soc. Ind. Mulhouse*, **1864**, 499. *Wagner's Jahresber.* **10**, 510.	Yellowish brown powder; deflagrates on heating.
7	Salicylic yellow A. (No longer in use)	Monobromonitrosalicylic acid.	 $C_6H_2\left\langle\begin{array}{l}CO\,OH\\OH\\Br\\NO_2\end{array}\right.$ $[CO_2H:OH=1:2]$.	Action of dilute nitric acid on monobromosalicylic acid.	1880	CHEM. FABRIK AUF ACTIEN VORM. E. SCHERING. Patents 15,117 and 15,889 (both lapsed).	A pale yellow powder, which melts when heated on platinum and then burns quietly. Very difficultly soluble in hot water; soluble in alkalis.

8	Salicylic yellow II. (No longer in use)	Soda salt of salicylic yellow A.	 $C_6H_2 \begin{cases} COONa \\ ONa \\ Br \\ NO_2. \end{cases}$	Ditto, and formation of soda salt.	Ditto.	Ditto.	Orange-yellow powder; deflagrates on heating. Forms a yellow solution in water. HCl—precipitates the free acid. NaOH—precipitate of the soda salt, which re-dissolves on warming, giving a brown coloration with zinc dust.
9	Salicylic orange. (No longer in use)	Soda salt of mono-brom-dinitro-salicylic acid.	 $C_6H \begin{cases} COONa \\ ONa \\ Br \\ (NO_2)_2 \end{cases}$	Action of nitric acid on monobromosulphosalicylic acid.	Ditto.	Ditto.	Orange-yellow powder, smells of bromine and deflagrates. Yellow solution in water and alcohol. HCl—precipitates the free acid. NaOH—no change.
10	Zinalin. (No longer in use)	Probably nitrified rosolic acid.		Action of nitrous acid upon rosaniline in alcoholic solution.	1870	M. Vogel. *Die Entwicklung der Anilin Industrie.* 2nd edition. Leipzig. 1870, 100.	Orange-red powder, insoluble in cold water; soluble slightly at the boil; easily soluble in alkalis.
11	Palatine orange. (No longer in use)	Ammonia salt of tetranitro-gamma-diphenol.	 $C_6H_2.(NO_2)_2ONH_4$ $\vert$ $C_6H_2(NO_2)_2ONH_4$ [OH : OH = 4 : 1']	Action of nitric acid on benzidine.	1869	Caro. H. Schmidt & G. Schultz. *Annalen*, **207**, 335.	Brown powder soluble in water, acids precipitate brown flakes of tetranitro-gamma-diphenol, melting at 220°. Does not deflagrate on heating.
12	Martius yellow. Jaune d'or. Naphthalene yellow. Naphthylamine yellow. Manchester yellow. Gamahl yellow.	Ammonia, soda, or lime salt of dinitro-alpha-naphthol.	 $C_4H_4 \begin{cases} C.(OH) - C(NO_2) \\ \vert \\ C(NO_2) - CH \end{cases}$	Action of nitric acid on alpha-naphthylamine or alpha-naphtholsulphonic acid.	1864	Martius. *Zeitschrift f. Chemie*, *N. F.*, **4**, 80. Ballo. *Naphthalene*, 1870, 61. *Ber.* **3**, 288. Darmstaedter & Wichelhaus. *Ber.* **2**, 113.	Ammonia and soda salts, small glittering crystals, lime salt yellow-red crystals. Soluble in water, ammonia salt is soluble in alcohol. Soda salt deflagrates, ammonia salt burns off quietly. HCl precipitates dinitro-alpha-naphthol melting at 138°.
13	Sun gold. Heliochrysin. (No longer in use)	Soda salt of tetra-nitro-alpha-naphthol.	$C_{10}H_3.(NO_2)_4ONa$ (alpha)	Action of soda solution on tetranitro-alpha-bromonaphthalene.	1882	Merz & Weith. *Ber.* **15**, 2721. Farbwerke vorm Meister, Lucius & Brüning. Patent 14,951 (lapsed)	
14	Croceïn yellow. [By] (No longer in use)			Action of nitric acid on beta-naphtholmonosulphonic acid B.	1881	Farbenfabriken vorm F. Bayer & Co. Patent 18,027.	A yellow crystalline powder.
15	Naphthol yellow S. Naphthol yellow. Citronin. Acid yellow S.	Ammonia, soda, or lime salt of dinitro-alpha-naphthol-sulphonic acid.	 $C_6H_3 \begin{cases} (1)\ C(OH) = CNO_2 \\ \qquad\qquad\quad \vert \\ (2)\ C(NO_2) = CH \\ (beta)\ SO_3H. \end{cases}$ (free acid.)	Action of nitric acid on alpha-naphtholtrisulphonic acid.	1879	Caro. Bad. Anilin & Soda Fabrik. Patent 10,785. Lauterbach. *Ber.* **14**, 2028.	An orange-yellow powder, easily soluble in water, the solution being turned pale yellow by acids, but not precipitated. Emits sparks when burnt.
16	Brilliant yellow [Sch].	Soda salt of dinitro-alpha-naphthol-monosulphonic acid.		Action of nitric acid on alpha-naphtholdisulphonic acid, Sch.	1881	Mensching. The Schollkopf Aniline & Chemical Co. Patent 10,57	Egg-yellow powder, which bubbles up but does not deflagrate when heated. Dissolves with brown-yellow coloration in water, acids produce no precipitate but turn solution pale yellow. NaOH orange yellow precipitate, soluble on warming. H_2SO_4 pale yellow solution.

No.	Commercial Name.	Scientific Name.	Constitutional Formula.	Formation.	Date of Discovery.	Number of German Patents, References, etc.	Reactions, etc.
17	**Citronin.**	Tetranitro- (with a little dinitro-) diphenylamine.	 $NH<\begin{smallmatrix}C_6H_3(NO_2)_2\\C_6H_3(NO_2)_2\end{smallmatrix}$ and $NH<\begin{smallmatrix}C_6H_4.NO_2\\C_6H_4.NO_2\end{smallmatrix}$	Action of nitric acid on diphenylamine.	1877—8	BROOKE, SIMPSON & SPILLER.

Conc. H_2SO_4—cherry red solution; on dilution, brown-red precipitate formed.

(To be Continued.)

—T. L. B.

Compound of Chromic Acid with Aniline. C. Girard and L. L'Hote. Compt. Rend. **104**, 1725.

IF saturated solutions of potassium bichromate and aniline hydrochloride be well cooled and then mixed together, yellow crystals of aniline bichromate $(C_6H_5.(NH_2)_2H_2Cr_2O_7)$ are readily formed. They crystallise in clino-rhombic prisms and are optically active; they are only slightly soluble in cold and are decomposed by boiling water. In alcohol they are only very slightly soluble, and gradually convert it into aldehyde: when gently heated they decompose, and when thrown on to mercury heated to 108 they burn away, leaving a residue of chromic oxide. With warm water a variety of violet colours is formed, while on addition of aniline hydrochloride and aniline, colours also result. Sodium, calcium and ammonium bichromates act similarly on aniline hydrochloride.—C. A. K.

The Colouring Matter of Lac-dye. R. E. Schmidt. Ber. **20**, 1285—1303.

LAC-DYE is obtained from the resin of certain trees in India, which are punctured by insects (coccus lacca). From these punctures the resin flows, which is known under the name of gum-, stick- and shel-lac. The colouring matter, or lac-dye, is obtained from the resin, probably by dissolving in water and precipitating the dye with lime and alum. The purification of the colouring matter is as follows:—Commercial lac-dye is treated with dilute H_2SO_4 at 90°, or HCl at the boiling point. The residue, which contains the larger portion of the colour and insoluble mineral substances, is washed and the colour dissolved in water and precipitated with lead acetate in the hot solution. The precipitate is washed, suspended in water, and the lead precipitated with H_2S. This solution is evaporated to dryness and extracted with alcohol. An insoluble powder—some of the colouring matter combined with iron, lead, and lime—remains. To the alcoholic solution 30 to 40 volumes of ether are added until no further precipitate forms. Some of the colouring matter and all the impurities are carried down. From the filtered solution the ether is distilled and the residue left to crystallise. An analysis of the crystallised product corresponds to the formula $C_{16}H_{12}O_8$. The author gives to the substance the name of laccaic acid. Caustic alkalis dissolve the colour and give a magenta solution. Baryta water forms a violet lake. Although laccaic acid resembles in many respects carminic acid (the colouring matter of cochineal), the two substances are apparently different in their properties, as well as in the shades which they give on wool and silk. A comparison of the absorption spectra of the two substances points to a close relationship between laccaic and carminic acids. Laccaic acids give a potassium salt of the formula $C_{16}H_9O_8K_3$, and a barium salt of the formula $C_{16}H_{10}O_8Ba$. With nitric acid it yields picric acid. Heated with concentrated HCl to 180°, a new crystalline body is formed and an inflammable gas, probably CH_3Cl or C_2H_5Cl, is given off. This new compound has the formula $C_{26}H_{14}O_{11}$. Laccaic acid is decomposed on fusing with potash. On dissolving the melt in water and steaming, part volatilises and part remains behind. The aqueous distillate contains acetic acid and a phenol. The non-volatile portion contains three substances. A body which is difficultly soluble in water and gives a red colour with Fe_2Cl_6; this the author finds to be oxyphthalic or oxyuvitic acid. The second compound, which gives no coloration with Fe_2Cl_6, gives on analysis numbers corresponding to oxytoluylic acid. The third substance has not been identified.—J. B. C.

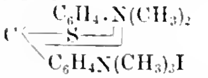
Formation of Oxyazo-compounds. B. Fischer and H. Wimmer. Ber. **20**, 1577.

OXYAZO-COMPOUNDS are formed by the action of phenols upon diazoamido compounds. The reaction proceeds best when the diazo-compound is added to the phenol, which should be heated a little above its melting point. Resorcinol and diazoamidobenzene yield dioxyazobenzene

$C_6H_5N_2C_6H_3(OH)_2$, resorcinol and diazoamido-*o*-toluene yield *o*-azotolueneresorcinol. Similar compounds are obtained with diazoamidoxylene and resorcinol, diazoamidobenzene and β-naphthol, diazoamido-*p*-toluene and β-naphthol, and diazoamido-*o*-toluene and β-naphthol. After heating the substances together for about half an-hour the product is poured into caustic soda solution and extracted with ether. The filtered alkaline solution is acidified with acetic acid and the new compound, which is precipitated, is recrystallised from alcohol.—J. B. C.

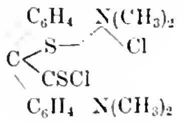
Tetramethyldiamidothiobenzophenone. O. Baither. Ber. **20**, 1731—1739.

This compound, which is manufactured commercially by the firm of Kern & Sandoz, has not yet been described. It melts at 202°, and occurs in the form of ruby red crystalline plates with a blue shimmer and also as a cantharides-green powder. The hydrochloride is prepared by passing HCl gas into the chloroform solution of the compound, and forms blue crystals. On heating the thiobenzophenone with HCl, tetramethyldiamidobenzophenone is formed, and H_2S is given off. A platinum double salt obtained by passing HCl into a solution of the thioketone was found to contain no sulphur, and gave, on analysis, numbers corresponding to one atom Pt, four atoms N, and seven atoms Cl. With concentrated nitric acid the thioketone gives trinitro-dimethylaniline. With hydroxylamine a reaction occurs in which H_2S is evolved, and an oxime is formed of the formula $C_6H_4N(CH_3)_2.CN.OH.C_6H_4N(CH_3)_2$. Methyl iodide combines with the thioketone to form a compound, which from its intense colouring power is not a ketone but has probably the following graphic formula :—



$$C\begin{cases} C_6H_4.N(CH_3)_2 \\ —S— \\ C_6H_4N(CH_3)_3I \end{cases}$$

Heated with zinc dust it is resolved into dimethylaniline and tetramethyldiamidodiphenylmethane, with thiophosgene in CS_2 solution it yields a colouring matter in the form of metallic golden green crusts, which dissolve in water. The colouring fades rapidly. This compound has probably the formula :—



$$C\begin{cases} C_6H_4\ N(CH_3)_2 \\ S—\ \ Cl \\ CSCl \\ C_6H_4\ N(CH_3)_2 \end{cases}$$

—J. B. C.

Carbazol Blue. E. Bamberger and R. Müller. Ber. **20**, 1903—1907.

Suida's compound is obtained by melting together carbazol and oxalic acid in the proportion of one of the former to 10—12 of the latter. The melt is extracted with hot water and benzene. The residue is dissolved in warm alcohol, filtered and evaporated. The alcoholic solution of carbazol blue when treated with glacial acetic acid, HCl, and zinc dust is decolorised. Filtered into caustic soda solution the leuco-base separates out as a white flocculent precipitate. On oxidation with any of the usual reagents the blue colouring matter is again formed. On the basis of this reaction and an analysis, which, however, is not entirely satisfactory, the authors consider the compound to be a triphenylmethane derivative of the formula :—

$$(HO).C \vdots (C_6H_3.NH.C_6H_4)_3.$$

—J. B. C.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

Improvements in the Preparation of Fuller's Earth for Use in Manufactures. F. Candy, Middlesex. Eng. Pat. 15,947, Dec. 28, 1885. 6d.

Fuller's earth in its natural state is ground in suitable apparatus, passed through a pug mill, formed into blocks, stacked, dried and pulverised, after which it is ready for use.—E. G. C.

Improvements in the Preparation of Fibre for Textile and other Purposes. T. Honywood, Horsham. Eng. Pat. 13,054, Oct. 13, 1886. 6d.

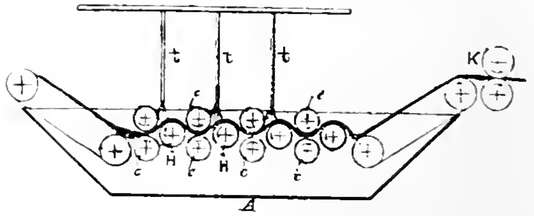
This invention relates to the treatment of the common nettle and allied species for the preparation of textile fibres. The bast and bark are separated from the wood and are then boiled in a solution containing soap jelly and either lime water, borax, soda or potash. This treatment may be preceded by a maceration in cold water.—E. J. B.

Improvements in the Method of and in Apparatus for Dressing or Sizing Textile Fibres. A. C. Henderson, London. From La Société Charles Vignet ses Fils et Cie., Lyon, France. Eng. Pat. 14,610, Nov. 11, 1886. 8d.

The method consists in producing immediate contact of the material to be sized with the sizing substance by means of rollers, a drawing of which accompanies the specification. The apparatus is specially adapted to light substances such as crape, net or tulle.—E. J. B.

New or Improved Process and Apparatus for Washing and Preparing Wool and other Fibrous Materials. W. H. Beck, London. From C. Delerue, Roubaix, France. Eng. Pat. 16,787, Dec. 21, 1886. 6d.

The wool or other material to be treated is drawn in between the rollers *c* placed in the washing vat A. The small "squirrel" rollers H prevent the fibres from lapping round the rollers c. Jets of water for washing are furnished by the pipes *t*. The washed fibre then passes through the squeezing rollers K. The object of the apparatus is to draw out the fibres while the material is being washed, thus rendering the subsequent carding operation unnecessary.—E. J. B.



Improvements in the Process of, and Apparatus for, Treating Ramie, Jute and other Fibres. C. C. Kauffman, New Orleans. Eng. Pat. 6464, May 3, 1887. 1s. 3d.

The process consists in drying the decorticated fibres by means of artificially-heated air, whereby the gummy matters in the fibre are solidified and rendered more easily removed by the subsequent mechanical treatment. The decorticated and dried fibres are then passed through the cleaning machine, the construction of which can only be understood by referring to the drawings and detailed description.—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

An Improved Method of Preparing Seaweeds and other Marine Objects for Ornamental Purposes. M. and C. L. Smout, Hastings. Eng. Pat. 9492, July 5, 1887. 4d.

The inventors claim the use of a solution of permanganate of potash, followed by treatment with a solution of acid oxalate of potash, for the purpose of bleaching the seaweed, sponges, etc. The bleached materials are then soaked in glycerine, or in a solution of a deliquescent salt, dried and finally shaken up in a box containing finely-powdered starch.—E. J. B.

VII.—ACIDS, ALKALIS AND SALTS.

Manufacture of Carbonate of Soda. Harrison Grey Dyar and John Hemming, London. Eng. Pat. 7713, Dec. 29, 1838. Second Edition, 6d.

This invention consists in the use of ammonium carbonate, sesquicarbonate or bicarbonate in the manufacture of sodium carbonate, by applying it to decompose common salt, and also in afterwards recovering the ammonia thus used in such a way as to allow of its being used again to convert fresh portions of salt into sodium carbonate. Successive portions of sodium carbonate are thus produced from the same portion of ammonia. As to the first part, common salt is dissolved in as much water as is barely sufficient to dissolve it, so as to constitute a fully saturated solution, and an equal weight of powdered ammonium carbonate is added to this solution. The mass is well mixed together and allowed to stand from ten to twenty hours, agitating from time to time to prevent the solid parts from settling before the reaction is complete. The liquid is then drained and pressed from the solid matters, which latter consist chiefly of sodium bicarbonate. To remove the excess of carbonic acid and to recover any ammonia contained therein, the mass is heated in a retort to 600° or 800° F. The vapours given off are condensed in a cooling chamber or refrigerating apparatus. The substance left in the retort is sodium carbonate. As to the second part, the liquid separated from the solid sodium bicarbonate contains ammonium chloride and carbonate, common salt and a small portion of the sodium carbonate formed. In order to recover the ammonium carbonate, the liquor is run into a still and heated, when water and ammonium carbonate distils over, which must be condensed. Or, instead of distilling over, a solution of calcium chloride is added to the mother-liquor, until the precipitate of calcium carbonate formed increases no longer. The latter is filtered, and the filtrate, now chiefly a solution of ammonium and sodium chloride, is evaporated to dryness and intimately mixed with powdered chalk. The mixture is heated in an iron retort until the ammonium carbonate, formed by this operation, is sublimed and separated. It is condensed in suitable chambers, into which the carbonic acid and ammonia vapours, given off on heating the sodium bicarbonate retorts, are also conveyed. The carbonic acid combines with the ammonia to ammonium bicarbonate, and if the amount of carbonic acid is not sufficient, more of it, obtained from any economic source, should be introduced. Furthermore, in order to complete the thorough recovery of the ammonia, a sufficient quantity of hydrochloric acid gas may be passed into the last of these condensing chambers, which acid gas will effectually retain the last traces of ammonia. The carbonate of ammonia thus reproduced or recovered is employed over again to convert fresh portions of common salt into sodium carbonate. It is essential for the success of the process to employ vessels or apparatus of such construction as to expose the ammonium carbonate as little as possible to the air, so that loss of ammonia may be prevented. The inventors claim as their invention: (1) the use of carbonate or bicarbonate of ammonia in converting common salt into carbonate of soda, and (2) the recovery of ammonia in combination with the first part of the process.—S. H.

A New or Improved Sodium Product and Method or Methods of Manufacturing the same. J. I. Watts and W. A. Richards, Sandbach. Eng. Pat. 13,001, Oct. 1886. 6d.

The new sodium compound is called "sesquicarbonate of soda," and is composed of one equivalent of sodium carbonate, one equivalent of sodium bicarbonate and two equivalents of water ($Na_2CO_3.NaHCO_3.2H_2O$). In manufacturing this compound, a solution containing three equivalents of soda to four equivalents of carbonic acid is prepared, and the solution is allowed to crystallise at a temperature not below 35° C. There are many ways of obtaining a solution of the right composition. The best appears to be to heat sodium bicarbonate so as to deprive it of about one-third of its carbonic acid and to dissolve the residue in hot water, or to add to a hot solution of 84 parts of sodium bicarbonate 106 parts of sodium carbonate. The solution, obtained by any of these methods, is clarified and slowly cooled, while it is kept agitated, when the sesquicarbonate crystallises out in distinct crystals, which are separated from the mother-liquor and dried.—S. H.

A New or Improved Continuous Furnace for the Production of Chlorine. E. Solvay, Brussels, Belgium. Eng. Pat. 13,389, Oct. 20, 1886. 8d.

This invention relates to a furnace for the continuous production of chlorine. In a mass of brickwork a series of hollow vertical columns is mounted, which receive the charge to be decomposed by heated air. These hollow columns are formed by placing one above the other a number of retorts made of fire-proof material, their diameter being very small in proportion to the total height of the columns, the heat having ready access to the material. The peculiar construction of the furnace has the further advantage of allowing all the parts to expand or contract freely in every direction, as the columns are really only a combination of separate segments. The whole series is heated from one gas-producer, the products of which are conducted by suitable flues to each column, round which they circulate. The temperature is regulated by opening or closing air-holes and the damper of the chimney. In carrying out the operation, the heated columns are filled from the top with the matter to be decomposed. A current of dried and heated air is admitted through the air-holes at the bottom of each column. The decomposed material is withdrawn continuously at the bottom, and the air, charged with chlorine, is conducted away from the top of the column.
—S. H.

The Manufacture of Hydrated Carbonate of Magnesia and other Products produced therein. W. Bramley and W. P. Cochrane, Middlesbrough. Eng. Pat. 13,762, Oct. 27, 1886. 4d.

To a solution of an alkaline bicarbonate or sesquicarbonate or ammonium carbonate magnesia is added, and the mixture is heated and agitated. Hydrated magnesium carbonate is formed, whereas the alkaline bicarbonate or sesquicarbonate is converted into carbonate. In the case of ammonium bicarbonate or sesquicarbonate the solution will, after treatment, contain ammonium carbonate or ammonia according to the amount of magnesia used. The operation should be performed in a closed vessel, to prevent loss of carbonic acid gas, and ensure more rapid mutual decomposition.—S. H.

Explosion of a Tube containing Crystals of Chromous Sulphate. J. M. van Bemmelen. Rec. d. Trav. Chem. des Pays Bas. 1887, **6**, 202.

The author prepared chromous sulphate, $CrSO_4.7H_2O$, as follows:—A solution of chromic chloride was reduced, precipitated by sodium acetate, the precipitate washed, dissolved in sulphuric acid, the solution crystallised, the crystals filtered, washed, dried and finally sealed in a tube, all the operations being conducted in an atmosphere of carbon dioxide. After being kept a year, protected from direct light, one of the tubes exploded violently. The crystals in this tube were not perfectly dry, their colour having changed from blue to green. The contents of the tube became liquid immediately after the explosion. No smell of acetic acid derivatives or of sulphurdioxide could be detected and only a trace of the latter appeared on distilling with dilute sulphuric acid. The author considers the explosion to be due to the water remaining with the imperfectly-dried crystals, which had gradually been decomposed, the oxygen going to oxidise the chromous salt, while the hydrogen was liberated and that the water of crystallisation of the salt, partially freed owing to the oxidation, had also been thus decomposed.—C. A. K.

Improvements in the Manufacture of Sulphuric Acid under High Pressure with Agitation, and in Apparatus for that Purpose. W. Burns, Leith. Eng. Pat. 14,441, Nov. 9, 1886. 8d.

The object of this invention is to form sulphuric acid of any required strength at one operation, by causing the chemical combination of sulphur and oxygen under high pressure. A is a cylindrical retort for burning sulphur, and C is a nitre pot. Both are placed horizontally in an oven with a fire-place F underneath them. The oven is heated, and as soon as the retorts are brought to the proper temperature, a blast of air from a blowing engine is injected into the retort A, to burn the sulphur. The sulphurous acid passes up the pipe D and down D′ into the vessel G, where it deposits any sublimed sulphur, and then up D″ into the mixer M. At the same time, the nitre in the pot C is decomposed by sulphuric acid from R and the liberated vapours pass up the pipe H into the mixer M. Atmospheric air from a blowing engine and high-pressure steam from a boiler are also blown into M. Here all the gases are thoroughly mixed, and on leaving the mixer, enter the large cylinder E, where they are deflected by the glass plate I down upon the surface of sulphuric acid contained in the basin L, whereby the vapours condense and form strong sulphuric acid, which overflows and falls to the bottom of the cylinder. The uncombined gases ascend and pass through the cup and ball agitators K, K, where the remainder of the sulphurous acid is converted into sulphuric acid and falls to the bottom. The remainder of the gases, consisting of nitrogen and nitrous acid, pass out by the pipe N into the cylinder O, which is filled with ammoniacal liquor or a solution of soda. Here they also meet a fresh supply of atmospheric air, which converts the nitrous acid into nitric acid, which in passing through the liquor forms a nitrate and, after boiling down, is used over again in the nitre-pot C. The remaining gases escape by the valve V, which can be weighed down to carry on the operation under any required pressure. Fig. 2 shows the construction of the ball and cup agitator. Z shows one of the balls forced up by the gas and the arrows show the direction the gases take in passing through the cups. The constant rising and falling of the balls keeps up a continuous agitation. In manufacturing on a large scale, three combining cylinders, E, are employed and in place of the sulphur retort, a vertical retort for burning iron pyrites is substituted. The specification contains illustrations of this and other modifications.—S. H.

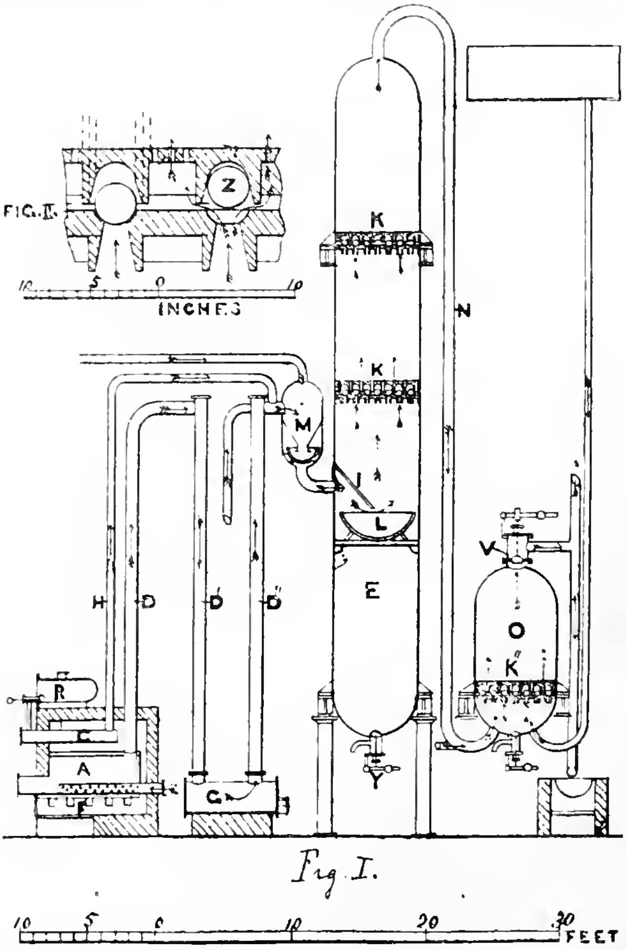


Fig. I.

Crystallisation of the Alkalis from Alcohol. C. Göttig. Ber. **20**, 1907—1908.

The author reserves the previous formulæ of his new hydrates of potassium and sodium hydroxide for further revision, as the substances were obtained from aqueous alcoholic solution and may contain alcohol of crystallisation.—J. B. C.

An Improved Apparatus for Using Liquid Carbonic Acid in Large Quantities. O. Brünler and C. G. Rommenhöller, Rotterdam, Holland. Eng. Pat. 9048, June 25, 1887. 6d.

In using liquid carbonic acid in large quantities out of the usual portable flasks, inconveniences occur owing to the supply of heat from outside being too small, as compared with the absorption of heat through the expansion of the liquid carbonic acid. In consequence, the gas inside the flask and passages in connection therewith, becomes "torpid," and causes obstacles in the working as well as danger. In order to do away with these drawbacks, the inventors fix a number of flasks in a frame and connect their outlet valves with a common gas-pipe, which lead to a small gas-holder.—S. H.

An Improved Apparatus for Impregnating Water with Carbonic Acid. T. R. Shillito, London. From C. G. Rommenhöller and O. Brünler, Rotterdam. Holland. Eng. Pat. 9994, July 16, 1887. 6d.

This invention is designed for application in conjunction with a "La Chapelle" apparatus for impregnating water with carbonic acid. Its object is to render unnecessary the mechanical power for driving the mixing machine by doing this with the driving force of the water to be impregnated. Carbonic acid from a gasholder and water from a well is drawn or forced by a pump into the mixing vessel. The latter usually contains an agitator driven from the main shaft, but according to this invention, a cylinder fitted with a small turbine, the shaft of which is provided with agitating blades, is placed underneath the mixing vessel, the turbine being driven by the partially-mixed carbonic acid and water passing to it through a pipe. When both are thoroughly mixed together, the water passes out into a collecting vessel.
—S. H.

The Present Position of the Leblanc and Ammonia-soda Industry. R. Hasenclever. Chem. Ind. **10**, 290.

In the last few years the consumption of sodium carbonate has steadily increased, but this increase has been exclusively supplied by alkali made by the ammonia soda process. In Germany 75 per cent., in France 60 per cent., in Austria 47 per cent., and in Great Britain 22 per cent. of the total production of alkali is made by this latter process. At the present time, 150,000 tons of 100 per cent. sodium carbonate are annually produced in Germany, compared with an output of 42,500 tons in 1878. Germany now produces more than its requirement, and although a small quantity has even been exported, the author thinks the export cannot be kept up permanently, as the raw materials for the manufacture of alkali are cheaper in Great Britain, which has also a better geographical situation for export. Since 1878, the price of alkali has decreased from £10 to £4 per ton. Previously 100kilos. of hydrochloric acid were calculated as costing 1 mark (1 shilling), but this price is too low at the present selling price of alkali. Consequently, certain branches of industry, which required a large amount of hydrochloric acid, as, for instance, Mond's or Schaffner's sulphur recovery process, had to be discontinued. The Rhenania Co. of Aix-la-Chapelle then tried to extract the sulphur from vat waste by Opl's process—viz., to drive out sulphuretted hydrogen by carbonic acid, and to use the former for the dissolution of more vat waste. Pure carbonic acid gas worked satisfactorily, but a mixture of 28 per cent. CO_2 and 0·5 per cent. to 1·3 per cent. O—gases from lime kilns—gave a bad result, as the oxygen proved troublesome, forming hyposulphites. It is the intention of the Rhenania Co. now to try H. v. Miller and Opl's modification, by which vat waste is first converted into calcium sulphhydrate, which latter is decomposed by steam into calcium hydrate and sulphuretted hydrogen, thus:

$$CaS + H_2S = CaS_2H_2.$$
$$CaS_2H_2 + 2H_2O = CaO_2H_2 + 2H_2S.$$

If this process could be cheaply carried out, a great advantage would result to Leblanc soda works. The competition between the two processes has lately become more acute, since the great depreciation of ammonia compounds, as well as improvements in apparatus, have been of the greatest benefit to the ammonia soda maker. In addition, the utilisation of the by-products of the ammonia soda industry is not lost sight of. Solvay has worked out his process of decomposing calcium chloride by silica so far, that the price of hydrochloric acid must not exceed a certain limit, whereas Mond experiments incessantly on the manufacture of chlorine from ammonium chloride. At present, nothing is known about the commercial value of these experiments.—S. H.

A Method of working up Stassfurt Potash-salt Liquors containing an excess of NaCl. H. Fischer. J. Prakt. Chem. **36**, 222—224.

It is well known the solubility of KCl and K_2SO_4 in water increases much more rapidly with temperature than that of NaCl; that the sulphates of potassium and sodium are less soluble in cold water than the chlorides; and lastly, that the solubility of all these salts, with the exception of KCl, is diminished by the presence of $MgCl_2$. Upon these facts is based the following method of working up liquors containing little potassium but much common salt; it has been found to work well in practice.

Mother-liquors rich in magnesium chloride are added until the quantity of $MgCl_2$ in solution is about one quarter the amount of NaCl. This produces immediately a partial precipitation of the common salt; and if the mixture is concentrated in a vacuum-pan below 100°, a further quantity of salt separates out, while the other chlorides and sulphates remain in solution. The salt thus obtained is fine-grained and contains 96—98 per cent. of NaCl. The liquor is boiled down to such a point that on cooling to the temperature of the air, all the potassium chloride remains in solution while the sulphates of potassium and magnesium crystallise out. The potassium chloride is recovered, partly as such and partly as artificial carnallite, by boiling down this and the successive mother-liquors in open pans. During this concentration the common salt still in solution separates out, together with a low percentage of sulphates: as soon as KCl begins to crystallise out the heating is stopped and the liquor transferred to the crystallising vats. The potassium chloride thus obtained is free from sulphuric acid.—D. E. J.

The Reaction between Sulphites and Nitrites. E. Divers and T. Haga. Ber. **20**, 1992—1996.

Claus and Fremy found that potassium sulphite gives with potassium nitrite, among other products, a salt $HON(SO_3K)_2$, which on heating yields $HONHSO_3K$ and $HKSO_4$. The authors have investigated the reaction with other nitrites and sulphites.

Silver and mercurous nitrite and SO_2 in excess yield sulphites, and NO and H_2SO_4 are formed; also after boiling, hydroxylamine may be detected. If, on the other hand, the solution is allowed to stand several hours without boiling, no hydroxylamine is formed.

Sodium nitrite and sulphurous acid yield NO and H_2SO_4, and also hydroxylamine. In the cold and with an amount of SO_2, just sufficient to decompose the nitrite, hydroxylamine is not formed but only after boiling. Sodium nitrite and sulphite solutions, when mixed, acidified and boiled, give hydroxylamine; with 1 molecule of $NaNO_2$ and 2 molecules of Na SO_3 almost the whole of the N present is converted into hydroxylamine. The solution of the two salts must be slowly acidified. Sodium metasulphite $Na_2S_2O_5$, when added to a solution of $NaNO_2$, acidified and boiled, yields hydroxylamine, and appears to be the best salt for the purpose.

Raschig has shown that potassium hydroxylamine sulphonate on boiling gives hydroxylamine. The authors recommend the use of the sodium salts in this reaction as being cheaper. These salts yield sodium hydroxylamine sulphonate, and also sodium amine sulphonate. On mixing the sulphite and nitrite the solution becomes alkaline, and absorbs CO_2 readily. In presence of CO_2 the reaction goes on with the formation of the amine-sulphonates, and after acidifying and boiling hydroxylamine may be detected in the solution.—J. B. C.

VIII.—GLASS, POTTERY AND EARTHENWARE.

Improvements in Machinery for Working Glass. E. H. Pearce, Birmingham, and H. Besson, London. Eng. Pat. 12,148, Sept. 24, 1886. 11d.

There are five claims in this patent, referring to machinery for grinding spectacle and similar glasses, to an arrangement for holding and manipulating large sheets of glass so that the edges may be "trued," bevelled, etc., and to other matters, detailed at considerable length in the specifications.—E. G. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

Blast Furnace Slag and Portland Cement. Knapp. Dingl. Polyt. J. **265**, 184–186.

THE author has recently observed a peculiar property possessed by blast furnace slag which he considers worthy of publication, seeing that the utilisation of slag for the production of hydraulic mortar is creating greater interest daily. In experimenting with Harzburg slag it was found that on digesting it with magnesium or ammonium chloride a considerable quantity of the lime was dissolved, whilst the silica remained unaltered. Portland cement exhibited the same property, magnesium chloride extracting from 14 to 18 per cent. of lime without absorbing even traces of silica. From these facts the author infers that both blast furnace slag and Portland cement contain free lime, which is taken up physically by the silica, thus forming a homogeneous mixture, the absorption in the case of cement taking place during the process of cementation, whilst with blast furnace slag the absorption is effected by solution during the operation of fusion.—D. B.

Sugar as a Cement. Herzfeld. Ztschr. f. Zucker-Ind. **37**, 499.

MORTAR containing sugar has been employed in building the new Natural History Museum in Berlin and has proved far superior to common mortar. It sets almost with the firmness of a good cement, while mortar made with molasses became soft and brittle after a time. In Madras a mortar is used with which either sugar, butter or buttermilk, shellac and eggs are mixed. It holds well and takes a marble-like polish—C. A. K.

Improvements in Making Portland Cement. A. Smith, J. Robertson and J. R. Andrew, Glasgow. Eng. Pat. 7539, May 25, 1887. 4d.

CLAY is taken as dug from the pit, without being dried, and mixed with the usual proportion of lime, a portion of which is used as limestone, the remainder as freshly-burnt lime. The burnt lime is first added in such proportion that the water in the clay exactly suffices to slake it and the heat given out effects the necessary drying. The limestone is then added and the mixture ground in a mill to the usual degree of fineness, made into bricks, calcined and the "clinker" reduced to a fine state of division as usual.—C. C. H.

Improvements in the Application of Various Inflammable Fluids and Substances to all kinds of Materials requiring High Temperatures in their Manufacture. R. Stone, London. Eng. Pat. 9458, July 21, 1886. 6d.

IN the manufacture of plastic and other materials, such as bricks, lime, gypsum, tiles, pottery, cement, etc., petroleum spirit, petroleum, tar or any other highly inflammable liquid, and vitriol are used, according to this invention, either together or separately as substitutes for ordinary fuel, such as coals or coke. Fibrous materials, as peat, sawdust, tow, hemp, old rope and refuse cotton waste, may be used for the absorption of the liquid fuels, which are sometimes also employed in the form of a spray thrown upon the incandescent mass. By the use of this invention, almost all kinds of refuse, including dust, coal dust, breeze cinders, ashes, clinkers, sewage and other materials, either ground or compressed, may be utilised.—E. G. C.

X.—METALLURGY, Etc.

Development of Ammonia in Working Iron. H. Wedding. Stahl and Eisen, **7**, 513.

G. W. GÖTZ, of the Otis Iron and Steel Company, Cleveland, Ohio, noticed that when a freshly-cast steel roller was broken, there was such a strong ammoniacal smell that it annoyed the workmen. The same thing occurred with an iron casting; this was only perceptible in great masses. It was specially perceptible when the steel contained 0·3 per cent. of carbon, 0·2—0·3 per cent. of silica and 0·9 per cent. of manganese.—W. E.

On Gautier's Investigations on Ferro-silicon and Iron Suitable for Foundry Purposes. H. Wedding. Stahl and Eisen, **8**, 562.

THE object of Gautier's investigations (this Journal, 1886, 606) was to dispense with the Scotch pig-iron, which was employed by French ironfounders as an addition to the different kinds of iron used for castings. The Scotch pig-iron was replaced by ferro-silicon, containing 10 per cent. of silicon, and it was shown that the favourable influence of the Scotch pig-iron on certain castings was due to the presence of silicon. A repeated heating and fusion of the iron oxidises the silicon and converts the graphite into amorphous carbon, and in order to maintain the chemical composition of the iron mixture, silicon must be added in some form. A mixture containing 2 per cent. of silicon is specially suitable for dense castings, as it prevents the formation of flaws. Owing to the application of ferro-silicon, the annual consumption of Scotch pig-iron in France has decreased from 200,000 tons to 20,000 tons. Wedding opposes Gautier's proposal on the point of economy. Since every iron mixture contains iron peroxide a portion of the silicon is used for the reduction of the peroxide, and this is evidently a waste of such an expensive article as silicon. Carbon is much cheaper as a reducing agent. Indeed, practical working has shown that the addition of the theoretical amount of silicon is insufficient; a larger or smaller excess, according to circumstances, is always required. As 10 per cent. ferro-silicon costs 97½ marks and 15 per cent. ferro-silicon costs 157½ marks, the author advises ironfounders to calculate carefully whether it is economical to replace pig-iron by ferro-silicium.—S. H.

Operating on Zinc Ore for Producing Chlorine, also Zinc, and the utilisation of said Zinc for Coating Metals Galvanically. J. Lea and H. R. Hammond, London. Eng. Pat. 10,868, August 25, 1886. 4d.

ZINC ORE (calamine) is treated with hydrochloric acid or an aqueous solution of chlorine and the solution of zinc chloride thus formed submitted to electrolysis. The zinc is deposited upon metals as a coating, or articles in zinc may be moulded by deposition, while the chlorine is used for operating upon fresh quantities of calamine.
—S. H.

Improvements in Machinery and Appliances for Treating, Dressing and Cleaning Tin and other Mineral Ores, and in Modes, Means and Processes connected therewith, and for other useful Purposes. G. M. Edwards, London. Eng. Pat. 12,729, Oct. 6, 1886. 11d.

THIS is a development of the sizing apparatus of Eng. Pat. 6347 of 1885 (see this Journal, 1886, 328). A series of vertical cylinders are so placed on an inclined plane or on steps, that the overflow from each cylinder is conducted into the bottom of that one next on the lower level. The first, or highest, of the series has a funnel connected with a large aperture at the lowest point on one side, and through this the slimes are introduced. It has also a telescopic cylinder, closed at its upper end, working within it at the upper part, the joint being rendered water-tight by an india-rubber ring; the object of this contrivance being the accumulation of water in the cylinder at will, to a level much higher than that in the next vessel. Each cylinder is supplied also with a four-arm radial agitator, working on the bottom; the agitator in the first being rotated, while those in the others are simply oscillated by an eccentric and crank movement, the motion imparted to each being less than that to the previous

one. Slimes are allowed to flow into the highest vessel to the full extent of the telescopic lining. The action of the beaters is suspended for a few seconds, and then a release of the inner cylinder causes a rapid overflow from the top of each pan to the bottom of the next throughout the whole series. The gradual diminution in rapidity of flow, coupled with the decreasing agitation in each successive cylinder, causes an efficient sizing of the ore. An automatic siphon arrangement may be substituted for the telescopic lining. After sufficient ore has collected in each vessel, it may be removed by any suitable sliding door, and may then be still further sized by passing alternately over and under partitions in a series of stepped chambers, in a continuous stream of water.
—W. G. M.

Improvements in Apparatus used for Coating Sheets of Iron and Steel, and Articles of Iron and Steel, with Zinc or Alloys of Zinc, or other Coating Metal or Alloy. R. Heathfield, Birmingham. Eng. Pat. 13,460, Oct. 21, 1886. 8d.

In addition to the brushes specified in Eng. Pat. 8390 of 1886 (this Journal, 1887, 512), a pair of revolving finishing brushes, preferably made of fine wire, similar to scratch brushes, is placed above the former for the purpose of surfacing the plate after coating. More than one pair of such brushes may be used and they may be employed in addition to, or in lieu of, the finishing rolls.
—W. G. M.

XI.—FATS, OILS AND SOAP MANUFACTURE.

Improvements relating to the Separation of Fat and Fatty Acids from Compounds containing the same. Wilhelm Graff, Bremen, Germany. Eng. Pat. 11,741, Sept. 15, 1886. 6d.

In treating water from wool-washing works, neutral calcium chloride is usually added, thereby precipitating large quantities of calcium carbonate. The inventor uses an acid solution of calcium chloride and to the precipitate obtained he adds caustic lime, in order to obtain calcium salts of the free fatty acids and of those combined with cholesterin or an alkali. This lime soap is dried on a steam bath, the non-saponifiable fats are extracted by benzine, etc. and the residue decomposed by hydrochloric acid.—W. L. C.

Improved Apparatus for Treating Waste Lubricating Oils. J. Stott, Bolton. Eng. Pat. 13,765, Oct. 27, 1886. 8d.

This is a description, with drawing, of an apparatus with cisterns, provided with sieves and water-gauges, through which the mixture of oil, water, metallic refuse, etc., is passed. The refuse is kept back by the sieves, the oil and water are separated by subsidence and the oil is used over again.—W. L. C.

XII.—PAINTS, PIGMENTS, VARNISHES AND RESINS.

On Cadmium Sulphide and the various Cadmium Colours of Commerce. G. Buchner. Chem. Zeit. **11**, 1087—1089, and 1107—1109.

Led by the great diversity of shades among the commercial cadmium colours, and the almost complete absence of reliable text-book information concerning them, the author has experimented with the different pigments and the methods employed in their production. When hydrogen sulphide is led into a neutral cadmium sulphate solution, the slight yellow cloudiness at first produced rapidly changes to a lemon-yellow precipitate; but when half of the metal has been thrown down, this precipitate darkens in colour until eventually it is of a dark Pomeranian or red-yellow shade; meanwhile about the period of half-precipitation a dark yellow scum forms on the surface, and there is a red ring around the margin and within the gas-tube; a small quantity of cinnabar-red, heavy, pseudo-crystalline powder collects also on the walls of the vessel. The precipitate after washing and drying may be separated by washing into a light and a dark coloured portion. But by filtering off the precipitate at half time, the collected portion darkens a little on drying, and the filtrate yields only the darker variety of sulphide. If the solution is warm or contains free acid before treatment (and Follenius has shown[*] that as much as 14% of 1·12 sp. gr. HCl may be present without hindrance to precipitation); the yellow stage is but evanescent, giving place immediately to one in which the colour is completely a full red. By using a different soluble salt of cadmium, a slight variation in shade will result; but an insoluble salt, treated while in suspension in water, always gives the dark product. The presence of neutral salts (NaCl, etc.) in the solution is without influence. But all these precipitates without exception are practically pure cadmium monosulphide (CdS): they contain no excess of sulphur, combined or otherwise, are similarly acted upon by reagents, are absolutely insoluble in water, and when suspended in the latter in pure condition are quite unaffected by air or hydrogen sulphide; they all, however, contain traces of the salt from which they were formed, which no amount of washing can remove and this is generally greater in the dark or red variety, in some cases amounting to even 4 per cent. of the sulphide. The chloride is the most obstinate in this respect, and may be removed only by prolonged heating in hydrogen sulphide; the small quantity of sulphur then deposited may be extracted by carbon bisulphide. Follenius suggested that this trace of undecomposed salt may effect the various colour alterations; but this is disproved by the fact that one finds similar shades with different percentages of impurity, and varying colours with the same quantity of foreign matter. The yellow is specifically much less dense than the dark variety, but in no sample has the author found any trace of structure or crystalline arrangement. He is convinced that there are two modifications only of the cadmium sulphide, one of a pure lemon yellow, the other of a full minium red colour; and that all the shades producible in the laboratory or obtainable in the market are mixtures of these two varieties in varying proportions. The alteration is simply molecular, the darker product being produced from the lighter by the condensation or aggregation of the molecules; so that to obtain a given modification, this aggregation must either be made as complete as possible or be prevented entirely. The yellow (or α-modification) is converted into the brown by the action of dilute acids or alkalis, and the more readily if it be *in statu nascendi*; hence, since by the action of hydrogen sulphide on a neutral cadmium salt a mineral acid is gradually generated in the solution, it is easy to comprehend why at a certain stage of the precipitation an aggregation of molecules is brought about. The red (or β-modification) becomes yellow for a moment immediately before solution in strong acids; and the interconvertible character of the two varieties may be observed by treating 1grm. of the red sulphide in a reagent glass with 1grm. of water and 3—5cc. HCl (1·124 sp. gr.) until it becomes yellow, and solution commences with evolution of SH_2; by then throwing the whole very rapidly into a large volume of cold water the β- will be found to have changed into the α-modification, and the reverse change will then gradually take place, owing to the presence of the diluted acid. The recorded formation of a CdS_5 described in Gmelin's hand-book as produced by the addition of potassium pentasulphide to neutral cadmium sulphate, is an error originated by Schiff (*Ann. d. Pharm.* **115**, 74). K_2S_3 and K_2S_5 produce respectively with $CdSO_4$ rapidly-subsiding sulphur-or-lemon-yellow precipitates, which become slightly red on complete precipitation, owing to the partial aggregation caused by a trifling excess of the potassium salt; a large excess causes re-solution of the cadmium compound. The pigment thus made is wanting in brilliancy; it consists of cadmium monosulphide with a variable excess of sulphur, extractable by carbon bisulphide and separable on treatment with hydrochloric acid. In regard to this

---

[*] "Contributions to the Knowledge of Cadmium, especially to the Quantitative Analysis of the same," Zeits Anal. Chem. 1874, Bd. 13.

precipitate, it is most important to note that, whilst the pure CdS, either in the α- or β-modification, is absolutely unaltered by light or air, all those products which contain free sulphur, finely divided by precipitation, become so completely oxidised when exposed to light, that the yellow colour passes in a short time into a dirty white, whether it be dry or moist, but most rapidly if rubbed down with linseed oil. This oxidation does not occur in the dark, nor can it be effected in any degree by mixing flour of sulphur with the monosulphide; it must be traced to the oxygen-carrying power of the precipitated sulphur, which is in this case so intimately mixed with the cadmium sulphide, and which is assisted greatly in its action by the oil—itself apparently not inactive as a carrier of oxygen. From these facts one may learn how great care should be expended in the choice of colours to ensure permanence, and how vast an influence may be possessed by an apparently insignificant impurity. The statement to be found in technological hand-books that the finest cadmium colours are made by the action of sodium monosulphide on the neutral sulphate, although apparently supported by theoretical considerations, since no free acid is formed in their production, is not borne out by the author's experience. Dilute cadmium solutions so treated give a bright yellow, concentrated solutions a dark yellow or red, and boiling solutions a brick-red precipitate. They are free from excess of sulphur, but will contain cadmium hydroxide or basic carbonate if sodium hydroxide or carbonate be present in the precipitant. The hydrosulphide behaves similarly. Cadmium hydroxide, like the sulphide, appears to exist in two modifications; and the action of hydrogen or sodium sulphide on these will produce a precipitate, coloured yellow or red according as the hydroxide is in the form of a bulky gelatinous precipitate (α-modification) or is heavy and finely flocculent (β-modification). The former of these may be produced by adding a solution of sodium hydroxide to one of a cadmium salt, the latter either by adding the cadmium solution to the caustic soda or by precipitating in boiling solutions. It would appear that the β-modification, with the red colour, is always the result of molecular aggregation; and this view is supported by the fact that an oxysulphide, $CdS.Cd(OH)_2$, which is formed when cadmium hydroxide is precipitated by sodium monosulphide (avoiding an excess of the latter), and which, of course, contains a double molecule, is of a red colour. This oxysulphide is regarded by the author as an intermediate stage in the production of the sulphide from the hydroxide, thus:—

$$(1.)\quad Cd(OH)_2 + Cd(OH)_2 = \left\{\begin{array}{l} Cd(OH) \\ Cd(OH)_2 \end{array}\right.$$

(2.) 
$$\left\{\begin{array}{l} Cd(OH)_2 \\ Cd(OH)_2 \end{array}\right. + Na\ S = \begin{array}{l} Cd-OH \\ \quad \diagdown S \\ Cd-OH \end{array} + 2NaOH$$

(3.) 
$$\begin{array}{l} Cd-OH \\ \quad \diagdown S \\ Cd-OH \end{array} + Na_2S = \begin{array}{l} Cd-S \\ \,|\quad\;\; | \\ Cd-S \end{array} + 2NaOH$$

It has a very fine red colour, of great brilliancy, but is less permanent than the sulphide when rubbed with oil; it dissolves completely in hydrochloric acid and gives up its oxide to acetic acid. The basic carbonate in its transformations resembles the hydroxide. The behaviour of cadmium sulphide at different temperatures is worthy of remark. It is quite non-sublimable, but maintained in air for some time at 135—140° C., it becomes superficially and only to a very slight extent, oxidised, losing at higher temperatures 2—3 per cent. of its weight partly by oxidation, partly by the loss of the acid of the trace of co-precipitated cadmium salt. As the temperature rises, the yellow modification gradually passes through dark yellow, orange and crimson to dark violet red, and on cooling returns through the same shades to its original colour; the red variety undergoes a similar play of colours, but on cooling becomes yellow, showing that the molecular aggregation has been dispersed. The final yellow is seldom a pure shade, but becomes tinged slightly with the brown of the oxide. There are a few varieties of the red sulphide which return to the original red except after long-continued or repeated heating; and a few α-modifications which become orange on cooling after protracted exposure to an even temperature without access of air.

Finally the author classifies cadmium pigments into three groups. (1.) *Pure Cadmium Colours.*—The best are those pure monosulphides produced, it may be in various physical modifications, by the action of hydrogen sulphide on cadmium solutions. They are unaffected by the media of the oil or water-colour artist, though less suitable for mixture with water-glass. Rubbed with linseed oil they undergo no appreciable alteration, even after a two years' exposure to light and air; even rancid oil of the worst description produced but a slight darkening. (2.) *Impure Cadmium Colours.*—Every trace of free acid or matter extractable by water, but above all of free precipitated sulphur, renders a sample unsuitable for use as a pigment. Impurities from the materials employed in manufacture, and cadmium hydroxide, carbonate, oxalate or phosphate must also be absent. (3.) *Adulterated Cadmium Colours.*—Flour of sulphur is believed never to be used for adulteration, nor has the author met with vermilion in the red pigments. The chief adulterants appear to be zinc oxide, sulphide and carbonate and cadmium oxide, carbonate, phosphate and oxalate; and these may amount to over 50 per cent. of the substance, A sample of colour for use as a pigment must satisfy the following tests, applied in each case to about 2grms. of colour:—(*a.*) HCl should effect complete solution, with evolution of SH_2, to a clear, or at most opalescent, liquid, which must give a yellow or orange precipitate with SH_2, and the filtrate from this must give no cloudiness with excess of NH_3 and $(NH_4)_2S$. An addition of ammonia in excess, and afterwards of calcium chloride, must produce no turbidity, nor must CS_2 extract more than the merest trace of sulphur. (*b.*) The moist CdS must be neutral to litmus, and digested with water, the solution must remain quite clear on the addition of $AgNO_3$ or $Ba(NO_3)_2$ (*c.*) The loss on heating must not exceed 3 per cent.; and after heating on platinum foil the residue must be red, yellow or orange-yellow, but never brown-tinged when cold. . The extract by acetic acid (1·06 sp. gr.) must not become turbid with KOH. (*d.*) After digestion with NH_3, the filtrate must be quite clear on the addition of an excess of HCl. (*e.*) They must be quite odourless, and if for use in oil-painting, absolutely dry—losing nothing at 100° C.

—W. G. M.

The Identity of Dambose and Inosite. Maquenne.

Compt. Rend. **104**, 1853.

In a series of researches on the composition of the juices of different plants yielding indiarubber, M. A. Girard has distinguished three new principles, "Dambonite," "Bornesite," and "Matezite," which he extracted from the gums of Gaboon, Borneo and Madagascar (*Compt. Rend.* **67**, 820; **73**, 426; and **77**, 995). These bodies behave as the methyl ethers of *dambose*, *Borneo-dambose and matezdambose*, a special variety of saccharine substances, non-reducible, non-fermentable, and which Girard has isolated by decomposing their methylic derivatives with hydriodic acid. Thus methylic iodide was disengaged. Having occasion to study a remarkable sample of pure *dambonite*, furnished him by the firm Billault and prepared according to Girard's prescription used for the caoutchouc of Gaboon, the author now finds a complete identity between *dambose* and *inosite* (*Compt. Rend.* **104**, 225). *Dambonite* may, perhaps, be considered as the dimethyl ether of inosite. Hence, there is no longer any need of retaining the name "dambose," since it is absolutely identical with the *inosite* contained alike in the vegetable and animal economies.—C. A. K.

Caoutchouc Yielding Plants. T. T. P. B. Warren.

Jour. Soc. Arts. **35**, 787—788.

After some brief remarks on the sources of the rubbers known as "Ceara," "Pernambuco," and "Mangaubeira," a description is given from the *Moniteur Officiel* (Feb. 1887) of the method for extracting caoutchouc from the *Sonchus oleraceus.* The plant is exhausted with carbon bisulphide and the residue obtained on evaporation treated with boiling alcohol. The insoluble matter, which is crude caoutchouc, is purified by warming with alcoholic potash and washing well with warm diluted alcohol. The yield is 4·13 per cent. of extractive matter, 0·41 per cent. of crude caoutchouc, which gives 0·16 when purified. An alternative process is to treat the plant with alcohol and then with benzene. After evaporating the solution, the residue (92 per cent. by weight of the whole plant) yields 0·27 per cent. of nearly pure caoutchouc on treatment with alcohol.—E. E. B.

XIII.—TANNING, LEATHER, GLUE AND SIZE.

Improvements in the Manufacture of Liquid Cement or Gum. E. M. Knight and A. H. Hobson, London. Eng. Pat. 13,168, Oct. 15, 1886. 6d.

To make one gallon of the gum about one and a half gallons of water, 3lb. of glue, 4oz. of borax and 2oz. of carbonate of soda, or an equivalent of any other alkali, are taken. The glue and alkaline salts are dissolved in the water by heat, and the solution is kept at a temperature a few degrees below boiling point for 5 or 6 hours. The continued application of heat renders the gum permanently liquid at the ordinary temperature. After allowing the sediment to settle, the clear liquid is evaporated to the required consistency.—B. H.

Improvements in Purifying and Graining or Bating Hides and other Skins, and in Apparatus Employed therein. T. Palmer, Bermondsey. Eng. Pat. 13,636, Oct. 25, 1886. 8d.

The patentee first describes the ordinary process of "bating" or "graining" hides, by means of a solution of pigeon or other birds' dung in water, and the use of the "new grainer," "mended grainer" and "old grainer." He then describes his improvements, by which he claims that a much larger number of hides can be "grained" in proportion to the amount of dung employed. Before submitting the hides to the action of the grainers, they are placed in a revolving drum and rinsed with water (preferably soft), at a temperature of about 70° F. The drum is rotated for about an hour. This rinsing removes a large proportion of the lime, so that the subsequent action of the grainers is to soften the hides. The hides are next stocked for 20—30 minutes, and are then submitted for about 45 minutes to the action of an old grainer. The hides, after draining, are then placed in a new or mended grainer. To make a new grainer, instead of placing the dung in the pit itself, the patentee places about 3 bushels of dung in a separate vessel and mixes it with about 130 gallons of water. The strong solution, after straining through a suitable sieve, is run into a grainer pit containing 900—1000 gallons of water. "A further improvement and economy" is effected by covering in the grainer pit, instead of leaving it open. For this purpose it is provided with a roof having one or more doors, for the introduction or removal of the hides. Drawings are given showing a grainer pit and drum, the pit provided with a roof as described.—B. H.

XIV.—AGRICULTURE, MANURES, Etc.

Examination of Beetroot Seeds. Pagnoul. Sucr. Indigène, 30, 68.

The quantities of phosphoric acid contained in sixteen varieties of seeds were determined and compared with the amount of sugar in the beets grown from them, with the result that no relationship between the two was evident.—C. A. K.

Agricultural Experiments on the Behaviour of Certain Plants towards the addition of Nitrogen as Saltpetre. G. Wolf and Kreuzhage. Landw. Jahrb. 1887, 16, 659.

From a series of experiments the authors conclude that cereals only grow well when the soil offers a sufficient quantity of nitrogenous nourishment, partly in the form of saltpetre. This also applies to potatoes, which need a considerable amount of nitrogenous matter, and in both cases the addition of manure containing nitre proved advantageous. Leguminous plants, on the other hand, did not appear to be influenced by the use of saltpetre manure, but they were found to have assimilated a large amount of nitrogen even after five months' growth in a soil containing little or no nitrogenous food. This assimilation of nitrogen by leguminous plants in cases where it is not supplied by the soil, appears extraordinary, and the authors suggest that it may be absorbed as ammonia from the air by the leaves or indirectly from the soil, which has itself absorbed the ammonia from the air; or, as may be possible in the case of a dry soil, the plants, owing to the presence of limestone, assimilate the free nitrogen of the air.—C. A. K.

Effect of the Manure used for Beetroot. Hellriegel. Ztschr. f. Zucker Ind. 37, 543.

The author finds that beetroot is more liable to decay on keeping when a phosphoric acid manure has been used, than when one containing Chili saltpetre has been employed and that this is especially the case when the beet is preserved under conditions of great heat and continued dryness.—C. A. K.

Action of Phosphoric Acid in Various Forms. Pommer. Ztschr. f. Zucker Ind. 37, 547.

The author compares the relative efficiency of superphosphate and Thomas slag as manures, and considers that while for the present superphosphate is of greater use, still further experiments should be made with Thomas slag, which appears to have the advantage that its effect is more lasting. When used the slag should be finely ground and evenly spread as early in the year as possible. It is specially good for moist and marshy land.—C. A. K.

On the Behaviour of Thomas Slag under Treatment with an Aqueous Solution of Carbon Dioxide. M. A. von Reis. Chem. Zeit. 11, 933—934 and 981—982.

These experiments are a continuation of others (see this Journal, 1886, 381), and are in reply to v. Maltzahn, who discredits the previous experiments in affirming the relative insolubility of phosphates in slags which have undergone igneous fusion. Eighteen phosphates have been treated and the results are recorded in tabular form. 10grms. of the finely powdered sample were exposed in a funnel to a flow of the carbonic acid water, at the rate of $\frac{1}{3}$ litre per hour. Tests made at regular intervals with one slag showed that the ratio of silicates to phosphates passing into solution corresponded fairly well with that in the original sample; that comparatively little silica or phosphoric acid are removed after 25 litres have passed; but that a somewhat greater proportion of lime was extracted even up to 50 litres. The decompositions are stated respectively as follows:—

$$Ca_4P_2O_9 + 6H_2CO_3 = CaH_4(PO_4)_2 + 3CaH_2(CO_3)_2 + H_2O.$$

$$Ca_2SiO_4 + 2H_2CO_3 = CaSiO_3 + CaH_2(CO_3)_2 + H_2O.$$

The remaining slags and compounds were examined only after passing two successive quantities of 5 litres each. Considerable differences appear in the relative solubilities of the phosphates—*i.e.*, the amount of phosphate dissolved as compared with that in the fresh sample—which are explained as arising from different combinations of the phosphoric acid. Thus, it was found that 42·1 per cent. of the phosphoric acid in calcium tetraphosphate were dissolved, while only 12·5 per cent. were extracted from the tri- and 16·8 per cent. from the diphosphate; bones (containing organic matter) yielded 28·5 per cent., bone ash, 5·5 per cent., and apatite, 3·1 per cent., the slags giving from 23 to 48 per cent. in the 10 litres. The silica thus extracted (relatively) from the slags varied from 50 to 85 per cent., the total lime from 40 to 57 per cent. The bulk of the magnesia appeared to be left in the undissolved residue. The experiments tend to confirm the accepted theory that the phosphorus in "Thomas" slags is present actually as tetraphosphate, and not as a mixture of triphosphate with free lime. The first action of aqueous carbon dioxide on tetraphosphate is to dissolve out any excess of CaO (if pre-existing) and then, after about 5 litres have passed, to extract the CaO and P_2O_5 in the constant ratio of 4 : 1, whereas the above mentioned mixture would continue to yield the lime in great excess up to the point of practical exhaustion. This research has an important bearing on the manurial value of the slags in question.—W. G. M.

The Phosphatic Deposits of Santa Maria di Leuca in Southern Italy. H. Spiodler. Chem. Zeit. **11**, 989.

THESE deposits occur between Gallipoli and Otranto, and consist of coprolites, bones, etc., embedded in a porous tertiary limestone. There are two beds, having a thickness of 19½ to 31½in. and extending for a distance of 160 yards along the shore. A phosphoric acid determination in numerous samples obtained from various parts of the bed and ground up together gave 7·4 per cent. P_2O_5 and the coprolites alone 8·7 per cent. P_2O_5. The phosphatic nodules contain a considerable amount of iron but no fluorine. How far these deposits extend inland has not yet been determined.—C. A. K.

Value of Different Varieties of Winter and Summer Wheat. A. Beseler and M. Märcker. Bied. Centr. **16**, 460—467.

IN these experiments twenty-one varieties of winter wheat and five of summer wheat were cultivated, as nearly as possible under exactly similar conditions; the yields, quality, etc., were noted, and other properties of the products were investigated. Tables of the results in detail are given, from which the following conclusions are drawn:—Large grain wheat generally contains a lower proportion of gluten than small grain. The swelling power of gluten is greatest in those cases where the amount of the gluten-nitrogen is in the greatest excess above that of the non-gluten nitrogen. It does not follow that flour richest in gluten is necessarily that containing the largest proportion of its total nitrogen in form of gluten-nitrogen. As regards baking qualities, on the average, summer wheat as compared with winter wheat contains more gluten; the swelling power of its gluten, both relative and absolute, is greater and the paste made from it is lighter, although there are varieties of winter wheat which produce lighter paste than some summer wheats. Bearded rivetts yielded the worst baking flour, although some non-bearded coarse white wheat proved good in the bakery. There is no regular relationship between baking qualities and either the quantity of gluten or the swelling power of the gluten contained in a flour; hence these factors alone are insufficient to determine the bread-making value of flour. The behaviour of these flours when mixed was not investigated.—D. A. L.

Agricultural Value of Different Varieties of Oats. O. Beseler and M. Märcker. Bied. Centr. **16**, 467—484.

SIXTEEN varieties of oats were cultivated, under similar conditions, on a warm humus loamy soil; their various valuable qualities were compared and estimated, and from the data obtained the following conclusions are drawn, which, of course, apply in main to the particular varieties and conditions of the experiments:—The best yielding varieties were Beseler's oats and oats of Swedish origin. Early maturing varieties yielded smaller crops than those varieties maturing later; the Duppauer variety was an exception, but it far exceeded all other early varieties in yield of grain. The amount of yield from the same variety in different years does not depend directly on the length of the period of vegetation. The best yielding varieties have not only the largest grains, but also the greatest number of grains to the ear. The weight per hectolitre varied from 40·8 to 56·1 kilos. in the different varieties, the smallest grained having, as a rule, the smallest weight per hectolitre. The amount of husks in the different sorts of oats varied from 22·8 to 29·9 per cent: the richest in albuminoids having the largest proportion of husk; whereas the grain poor in albuminoids had a larger proportion of its protein in the husk than grain rich in albuminoids. Only 4·5 per cent. of the nitrogen of the oats was contained in the husk, and on an average only 5·3 per cent. of the total nitrogen was non-albuminoid. The absolute germinating power was about the same in all the varieties, but the energy of germination differed considerably, generally being least in those grains containing most albuminoids; these were frequently the smaller grains which were generally richer in albuminoids than the larger grained varieties of oats, but all small grain oats are not rich in albuminoids. In the varieties cultivated, richness in albuminoids did not accompany abundance in crop-yield, in fact, the varieties yielding the smaller crops were in many cases characterised by a high percentage of albuminoids. The early varieties had a higher percentage of albuminoids than the late varieties, but the latter yielded the larger quantity of albuminoids per acre. In many cases richness in albuminoids was associated with a low percentage of fat, but there were several exceptions to this. During the season 1886 seeds poor in albuminoids also yielded crops poor in albuminoids. By Stutzer's method, 94 per cent. of the nitrogenous matter of the oats was found digestible, an amount greatly in excess of any results obtained by direct experiments with animals. The amount of nutritive matter produced per acre differs very greatly in the various kinds of oats; and from a financial point of view for every £5 value of nutritious matter obtained from the lowest yielding variety, a value of £6 10s. was got from the highest yielding variety. Hence showing the importance, in farming, of selecting a variety of oat suitable to the surrounding conditions.—D. A. L.

XV.—SUGAR, GUMS, STARCHES, Etc.

Decomposition of Cane Sugar by Boiling with Lime. W. Niedslag. Deutsche Zucker Ind. 1887, 159—160.

IN reference to the so-called "undeterminable loss" of sugar during its extraction from sugar-beet, the author shows experimentally the decomposition of sugar by boiling with lime. On boiling with lime, 250grms. of cane sugar were almost entirely decomposed at the end of twenty-one days, forming an amorphous calcium salt. Heating cane sugar for seventy-two hours with lime, strontia and baryta, respectively, caused a loss of sugar and more especially of the crystallisable portions; the baryta was most energetic in its action.—D. A. L.

A Carbohydrate contained in Acorns. C. Vincent and Delachanal. Compt. Rend. **104**, 1855.

AFTER isolating quercite from acorns by further concentrating the extract after the removal of the potassium and calcium salts as sulphates by concentration and addition of alcohol, the author found that after a good yield of quercite had been obtained, the mother liquor yielded a small quantity of large transparent crystals. These formed hexagonal prisms, contained water of crystallisation and effloresced in the air. The substance is a hexatomic alcohol and has the formula $C_6H\ (OH)$, isomeric therefore with inosite, from which however it is distinguished by its crystalline form and physical properties. It melts at 342° (inosite at 217°), its hexacetyl derivative at 301° (that of inosite at 212°) and dissolves in 66 parts of water at 15°. The author suggests the name *Quercin* for this new body.

—C. A. K.

On the Storage of Diffusion Residues of the Sugar Works, and Experiments on the Loss resulting from the same. K. Müller. Hildesheim. land-u-forstw. Vereinsbl. 1887, 1.

SATISFACTORY results have accrued from the application of Fry's sweet ensilage system to the residues of the diffusion process: these should be mixed with thin milk of lime, pressed in a Klusemann press and packed closely (now containing 20—30 per cent. of dry substance) in the silo. The silo consists of a deep pit with steep, cement-covered walls, covered airtight with roofing felt or similar material and so weighted with bricks that the ensilage matter is subjected to a pressure of 50kilos. per square foot. The pit may be opened after five months and the contents used as fodder. In an experiment recently made, 90 kilos of the shavings had lost but 1 kilo. in five months and were then eagerly eaten by the cattle.

—W. G. M.

Direct Extraction of Sugar by means of Alcohol. Zeits. f. Zucker Ind. 1887, 371.

HERZFELD has tested Trobach's patented method (see this Journal, 1884, 376), and finds it to possess the following advantages:—The direct production of refinable sugar, the concentration of nearly all the nitrogen in the molasses and the use of the shavings as a fodder. But the consumption and loss of alcohol by distillation and frequent rectification are so great as to utterly preclude the practical use of the process. Moreover, the purity of the alcoholic product is but little higher (3 per cent.) than that resulting from the use of water.

—W. G. M.

Improvement of the Press Method. Bull. Soc. Chim. 1887, 203.

BOYER has found that the impurities carried into the sap. when beet pulp is heated to 70—80° before pressing, could be retained in the pulp, not by calcium bisulphite, but by a small addition of lime (0·2 litres of milk of lime of 20° per 100 litres of water).—W. G. M.

The Quantity of Juice and Marc in abnormal Sugar Beet. G. v. Lippmann. Bied. Centr. **16**, 449.

IT is frequently asserted that sugar-beets are poor in juice when they yield their juice and diffuse with difficulty. The author, however, in common with some other investigators, finds these abnormal beets contain the ordinary amount of juice, 94—95 per cent. (see this Journal, 1887, 445). The difficulty in diffusing them (due to the peculiar swelling of the pulp-portions) may be removed by using slightly alkaline water for the extraction or by treating the sections with milk of lime.

It is shown, moreover, that the mode of extraction influences results in analysis; thus by the use of hot or cold water, of weak or strong alcohol or methyl alcohol, etc., a difference of over 1 per cent. in the quantity of marc was obtained.—D. A. L.

Estimation of Raffinose. R. Creydt and C. Scheibler. Bied. Centr. **16**, 487—488.

CREYDT is perfecting a method for the estimation of raffinose. Scheibler, taking advantage of the solubility of raffinose in methyl alcohol, has the following method for estimating it in spike sugar:—The sugar under examination is digested with a saturated solution of sugar in methyl alcohol in which the polarisation has been previously determined. If the sugar is pure no change is observed; on the other hand, raffinose, if present, dissolves and increases the polarisation of the solution. Inversion methods are, however, of greatest importance and wherever in question should be set right. Clerget found when cane sugar is polarised, then inverted by heating with acid and again polarised, that for every 100° of original right-handed rotation at 20° C., 34° of left-handed appeared; this was confirmed by Tuchschmidt. Creydt, and also Wolff, working with 3·024grms. of sugar in 50cc., with 5cc. concentrated hydrochloric acid and heating ten minutes at 68° C., then diluting to 100cc., found 32° instead of 34°, but on using the same quantities as employed by Clerget they also were able to confirm his number.—D. A. L.

Extraction of Saltpetre from the Salts from Sugar-beet Molasses in France. Bied. Centr. **16**, 485—486.

WHEN sugar-beets are heavily dressed with nitrogenous manures, nitrates are found in abundance, both in their juice and in the molasses obtained from such juice. Some molasses of this description on dialysing yielded a dialysate, which on evaporation deposited a crystalline mass of the following composition:—KNO_3, 48·90; KCl, 34·70; K_2SO_4, 1·87; sugar and organic matter, 7·96; insoluble, 0·92; water, 5·95 per cent. resp. By dissolving this mixture in hot water and cooling to 70° C., when the gravity equals 38° B., the potassium chloride crystallises and the liquid is easily removed. On further cooling the nitre is deposited and by simple digestion in a solution of nitre and whizzing, may be purified to a fineness of 90 to 98 per cent.—D. A. L.

XVI.—BREWING, WINES, SPIRITS, Etc.

Improvements in or appertaining to Compounds applicable for the Manufacture therefrom of Ale, Stout, Porter, Lager and other like Liquors; and in Apparatus for making said Compounds. E. Manbré, Garston. Eng. Pat. 12,291, Sept. 28, 1886. 8d.

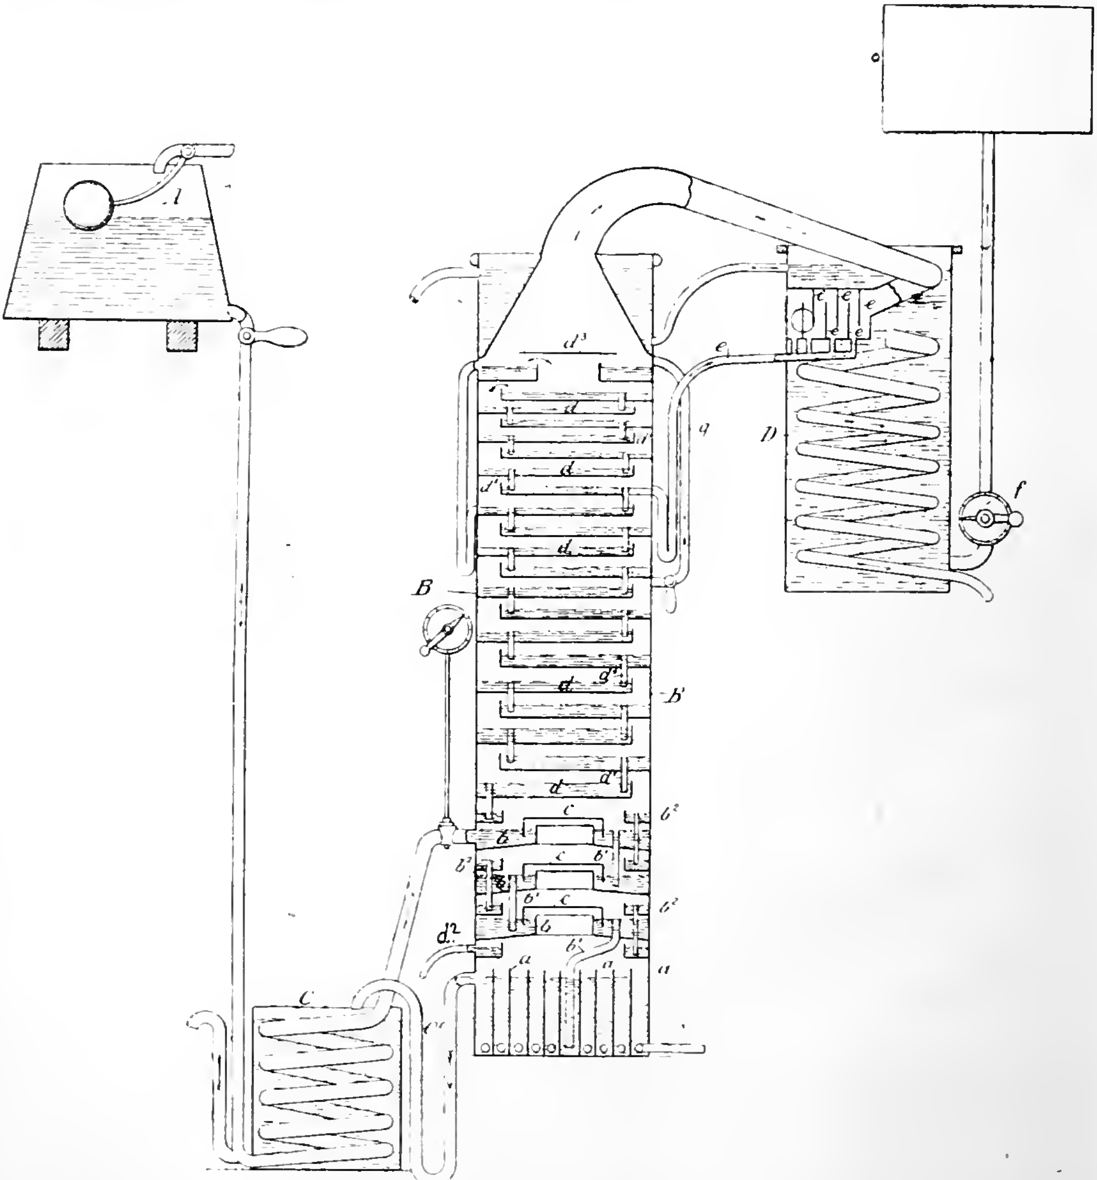
A WORT is prepared in the usual manner and when all the starch has been converted, it is heated under a pressure of 60lb. to 90lb. with a small quantity of alkali in order to free it from oil, nitrogenous matters and easily volatilised salts and acids. An extract of hops is then prepared by boiling hops in distilled water under a high pressure and temperature. The two solutions are then mixed, concentrated and used for the above purposes in this state. A drawing of the apparatus employed accompanies the specification.—G. H. M.

Improvements in or applicable to the Manufacture of Grape Wines. W. Wild, London. Eng. Pat. 10,108, July 19, 1887. 4d.

THIS embraces the preparation of a pure grape-must by the concentration in vacuo of fresh grapes. Unfermented and fermented still and sparkling grape wines can be prepared from this concentrated must by dilution with water and aëration with carbonic acid gas or by fermentation, as the case may be.—G. H. M.

An Improved Mode of, and Apparatus for, Distilling and Maturing Alcohols. J. Wallace, London. Eng. Pat. 7190, May 17, 1887. 8d.

THE object of the apparatus described in this specification is the production of alcohol free from fusel oil and acetic acid, the absence of which is the characteristic of spirit which has been "aged," and an increased yield from a given quantity of grain, which the patentee states amounts to about 10 per cent. A is the wash charger feeding the wash continuously through the heater C, kept full of spent wash, to the still column B. The lower part of the still column is formed into a boiler *a*, heated by a steam coil lying between the convolute partitions. *b*, *b*, *b*, are the distilling trays, each consisting of an annular space connected to the next tray lower by overflow pipes *b*¹; C is a baffle preventing the steam and vapour from passing through the centre of the still without passing through the wash on the trays *b*. *d*, *d*, *d*, are the rectifiers charged at the beginning of an operation with cold water; they communicate with each other by an overflow pipe, and compel the vapours to follow a circuitous path. The fusel oil condensing on the rectifiers finds its way to the rings b^2 at the lower part of the still and out by the pipe d^2. D is the condenser in which the rectified and pure spirit is finally condensed, after passing through a baffle plate-box e, e, e, which removes the last traces of fusel oil. The condensing water is supplied to D from an overhead cistern, through a regulating valve *f*; the quantity of water supplied to this vessel regulates the purity or "age" of the finished spirit.—C. C. H.



XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(*A*) CHEMISTRY OF FOODS.

New Method of Preserving Butter. Board of Trade Journal, Sept. 1887.

THE French *Moniteur Industriel* states that M. Pierre Grosfils, of Vervier, has communicated to the "Société d'Encouragement de Vervier" a note on his process for preserving butter. After having enumerated the causes which led last year to the lowering of the prices of dairy produce, and especially of butter, he dwells upon the unfortunate results of the over-production of this article, and on its falsification by means of oleomargarine. He has discovered a way of preserving butter, without alteration, for a long period, so that it can be imported into countries the climate of which does not permit it to be made there. The process has been subjected to practical experiments for more than six months. M. Grosfils describes the various phases of his research as follows:—He first mingled 1grm. of salicylic acid with 1 kilo. of butter, but after some weeks the product had altered. He thought that the cessation of the antiseptic action of the acid was due to its crystallisation in the non-liquid substances which were mingled with it. After numerous experiments, he found that lactic acid prevents this crystallisation. This acid is, in fact, a good solvent for salicylic acid; it has the advantage of being hygroscopic, of possessing antiseptic power, and, finally, of being uninjurious in food.

The first result of the discovery of M. Grosfils was to be able to diminish the amount of salicylic acid used to preserve the butter. Instead of mixing 1grm. of acid per kilo., he put the butter in a liquid containing ·05 per cent. of salicylic acid and 3 per cent. of lactic acid. He successively divided the salicylic acid into still smaller doses, until at last he had the proportion of 1grm. of acid to 5000 parts of water. The final composition consisted then of 98 parts water, two parts lactic acid, and 0·0002 of salicylic acid. This composition allows of the indefinite preservation of butter of good quality, even at a high temperature and in hot countries. If the butter has already undergone some alteration, a stronger dose must be used.

But the author points to the following fact:—The lactic acid contained in the antiseptic liquid in doses stronger than 2 per cent. gives the product a taste which, without being offensive, is a little too sour to leave the article saleable. In such case the butter should be washed with water, or better still with scalded milk, to which a little carbonate of soda has been added to prevent any coagulation of the casein. This washing will not only remove the lactic acid and its taste, but also the salicylic acid in solution, to such a degree that what remains will be imperceptible.

The process is stated to be most economical, as the antiseptic liquid will serve indefinitely, being unalterable. Care must be taken each time to use the same quantity of butter.

The preparation of a kilo. of butter by means of this process, it is stated, will not cost more than one or two centimes.—C. G. C.

Examination of Milk. R. Frühling. Rep. Anal. Chem. **7**, 517—523.

This paper contains a detailed description of the methods adopted for testing once a month, both morning and evening, an average sample of the milk yielded by about 17 cows at a dairy for "nursery milk." In order that the quality of the milk might be as uniform as possible throughout the year, dry food only was used, the nature and quantity of which is also fully described.

The average composition of the milk, tested monthly from January to December, 1886, was:—

	Evening.	Morning.
Fat	3·00	2·84
Proteïds	3·96	3·92
Ash	0·72	0·72
Milk-sugar	4·43	4·39
Water	87·89	88·13
	100·00	100·00
Sp. gr. at 17·5°	1·0325	1·0307

All the monthly analyses are published in full. The milk and cream obtained were quite white, but experiments showed that these became yellow again if green food was provided.—E. E. B.

New Researches on the Behaviour of Proteïds when treated with Digestive Ferments. A. Stutzer. Zeits. f. Physiol. Chemie, 1887, 529.

From the newer researches of the author (*Chem. Zeit. Rep.* **11**, 56) it appears that peptic digestion is best effected by warming 1grm. of the substance under examination for 12 hours with a pepsin solution containing 0·2 per cent. of hydrochloric acid. The quantity of the latter solution to be employed will depend upon the percentage of total nitrogen in the proteid—viz., 100cc. for bodies with less than 5 per cent. of N, 200cc. for those with 5—10 per cent., and 400cc. for those holding more than 10 per cent. When more than 1grm. of substance is used, the amount of pepsin is proportionately increased. A solution with 1 per cent. of HCl will dissolve a somewhat greater quantity of nitrogen than one with 0·2 per cent. By successive treatment with acid pepsin solution and alkaline pancreatic fluid, the amount of undigested nitrogen remained almost identical, whether the former contained 0·2 per cent. or 1 per cent. of HCl. The pancreatic fluid, made according to the author's directions, acts more readily in dilute alkaline solution than when neutral; but a slightly greater or less quantity of sodium carbonate is a matter of indifference. The dried pancreatic preparations of commerce simply dissolved in water are able to dissolve more protein than when 0·25 per cent. of sodium carbonate is present.—W. G. M.

Improvements in or applicable to Packages for Canning or Preserving Articles used as Food, or in Plates applicable for the Manufacture of the same. W. Powell, Liverpool. Eng. Pat. 9932, Aug. 21, 1885. 6d. Amended specification.

The title and body of this specification were amended July 2, 1887. Tin plate, sheet-iron, steel or other thin metallic sheet, is coated with mucilage or cement, rendered antiseptic by salicylic acid; a sheet of *papier mâché* or paper is applied thereto, passed through rolls and dried. The paper prevents injury to the contents of "tinned" packages by contact with the metal.

—C. C. H.

(*B*) SANITARY CHEMISTRY.

Notes on Crude Carbolic Acid and its Substitutes. Alfred H. Allen. A paper read before the British Association. Brit. and Col. Drug. 1887, 364.

A variety of substances has been employed and patented as bases for the manufacture of carbolic powders. Thus, the oldest preparation of this kind is made by adding a certain proportion of crude carbolic acid to a crude sulphite of calcium, prepared by passing sulphurous acid gas over ignited limestone. Sulphurous acid is introduced into other powders by the direct addition of a solution of calcium bisulphite, and the use of other sulphites has also been patented. Carbolic and other powders are made by adding carbolic acid to silica in various forms, to peat, spent gas lime, etc. A mixture of bleaching powder and carbolic acid has also been employed. Soluble salts have been used as absorbents of carbolic acid, the resultant powder being more readily removed and less likely to choke up drain pipes than the preparations commonly employed. "Borophenol," a similar preparation, is made by absorbing carbolic acid in dried borax.

Although the term carbolic acid has been extended commercially so as to include products consisting chiefly of cresylic acid and still higher homologues of phenol, it appears a straining of its legitimate signification to apply it to products from which the real carbolic acid has been previously extracted. This, however, is sometimes done, but the matter becomes more serious when the article is purposely mixed with neutral tar-oils or other hydrocarbons of little direct value as antiseptics; and this has been done to the extent of fully 50 per cent.

Another practice which is increasing is the complete or partial replacement of carbolic or cresylic acid from coal-tar by the mixture of crude phenoloid bodies obtained from the tar or oil produced by condensing the waste gases from coke-ovens or blast furnaces burning bituminous coal. "Blast-furnace creosote oil" is now produced in enormous quantities in Scotland, and has already found an extensive application for creosoting timber, for producing the "lucigen" light, and as a liquid fuel. It contains from 20 to 35 per cent. of phenoloid bodies soluble in caustic soda, as against 5 to 10 per cent. in coal-tar creosote oil of London make (Newcastle coal).

Here there is a cheap and abundant source of phenoloid bodies, but it is evident that the unacknowledged substitution of them for coal-tar acids is objectionable, even assuming them to be comparable to the latter in antiseptic value.

Our knowledge of the phenoloid bodies extracted by caustic soda from blast-furnace creosote oil is chiefly due to the researches made by Watson Smith. He found a sample of phenoloids, extracted from Gartsherrie tar, to contain only 1·33 per cent. of real phenol boiling at 182° C., whereas the tar acids from Lancashire coal-tars yield about 65 per cent. of crystallisable carbolic acid. The fraction which would contain the *cresols* (cresylic acid), amounted to 4·5 per cent. of total phenoloids. The larger fraction (19·4 per cent.), distilling between 210° and 230°, he regarded as probably consisting mainly of a mixture of the xylenols, $C_8H_9.OH$. A large proportion of the phenoloids distilled at a temperature above 230°, but its nature requires further study. The fraction distilling above 360° gave, on treatment with soda and exposure to air, unstable colouring matters, which are probably allied to the eupitonic acid obtained from wood-tar. The tars obtained by condensing the gases from gas-producers and Jameson's coke-ovens contain phenoloid bodies not unlike those of blast-furnace tar. Similarly, the crude oil or tar produced in Scotland by the distillation of bituminous shale yields to soda phenoloid bodies to the extent of 1 or 2 per cent. Creosol seems to be wholly absent, but on the other hand, *phlorol* is present, as also a *cymenol* ($C_{10}H_{13}.OH$), boiling at 237° and two phenols isomeric therewith. The pyrogallic ethers, boiling respectively at 253°, 265° and 285°, found by Hoffmann in wood-tar creosote, have also been isolated from the shale product, together with other bodies of very high boiling point which have not yet been fully examined.

These results show that a similarity exists between the phenoloids of low temperature tars, whether they be obtained by the distillation of wood or shale, or by the condensation of the gases from blast-furnaces, coke-ovens or gas-producers. In minor though important points, differences exist, but they seem to present a greater resemblance to each other than they do to the coal-tar phenols.

A well-known firm is now preparing an antiseptic from these phenoloids of blast furnace tar. At the author's suggestion they have adopted for their product the name "Neosote," a word which signifies "new preserver," or "new preservative," and may serve to suggest its similarity to creosote. The crude mixture of phenoloid bodies obtained by treating blast-furnace tar with alkalis is subjected to a process of further purification, which greatly improves it. Thus, the strong disagreeable odour of the crude product is destroyed and the highly irritating and acrid bodies are also removed. These objectionable constituents are probably identical with or closely allied to the *cærulignone* of wood-tar creosote, a single drop of which causes bleeding when placed on the tongue.

"Neosote," freshly prepared from blast-furnace tar, is almost as colourless as water but it acquires a sherry colour by keeping. Experiments made to test its antiseptic value indicate that it is fully able to compare with crude carbolic acid, while its caustic properties (when applied in a concentrated condition to the skin) are very much less marked than those of the coal-tar product. In short, when properly purified, neosote presents a considerable resemblance to wood-tar creosote.

The Antiseptic Properties of some of the Fluorine Compounds. Wm. Thomson. Chem. News, **56**, 132.

THE author finds that the compounds of fluorine, hydrofluoric acid, the acid and neutral fluorides of the alkalis, and also their fluosilicates are powerful antiseptics, and possess besides the advantages of being non-volatile and not destroyed by oxidation. Of these compounds the sodium fluosilicate seemed the best suited for the general purposes of an antiseptic. This salt is not poisonous, possesses no smell, and is sparingly soluble in water. Possessing only a slight saline taste, it may be employed for preserving articles of food without communicating any taste to them. As regards uses in surgery, it may be remarked that a saturated aqueous solution containing 0·61 per cent. of the salt is, it is stated, not irritating to wounds, while it possesses greater antiseptic power for animal tissues than one part of mercuric chloride in 1000 of water.—W. S.

Purification of Water. Ztschr. f. Zucker Ind. **37**, 498 and 599.

COMMUNICATIONS on the purification of the waste water from sugar factories by Sickel, Handtmann, Schattmann, Herzfeld and Stammer point out that no method yet known is generally applicable, and that methods of purification by chemical means are objectionable, since, although they clear the water, they do not serve to remove the injurious impurities (sugar, gum, etc.), for as the alkalinity of the water gradually disappears, decomposition and fermentation again set in. Further, it is stated the fish are often not killed by the organic impurities of the water, but by the ingredients introduced in the purification, especially the large amount of alkali, though the results of the experiments on this point are not concordant. Nevertheless, purification by chemical means is recommended where the neighbourhood is annoyed by rapid decay and fermentation taking place in the polluted water. The authors consider such purification sufficient.—C. A. K.

Manufacture of a Composition for Softening and Purifying Water. H. R. Lipscombe, London. Eng. Pat. 12,061, Sept. 22, 1886. 4d.

DRY slaked lime, 40 parts, is mixed with sodium carbonate, 50 to 60 parts, or an equivalent quantity of potassium carbonate, phosphate of sodium 2 parts and one part each of potassium permanganate, oxide of manganese and ammonium carbonate. The compound is added to the water to be softened. "Generally 1lb. of the composition will suffice for softening 200 gallons of water."
—C. C. H.

Improvements in Furnaces for the Desiccation, Deodorisation and Combustion of Animal and Vegetable Matters, or Town's Refuse. T. Ogden, Burnley. Eng. Pat. 12,248, Sept. 27, 1886. 11d.

THE refuse or matter to be desiccated is placed in an oven underneath the bars of a furnace constructed in the ordinary manner. The products of combustion from the furnace divide at the farther end of the furnace and are carried by flues, circulating in opposite directions, round the sides and underneath the floor of the oven, passing from thence to a shaft. The gaseous products of dessication rise from the oven and pass through the furnace, mingling with the products of combustion; they are thus completely destroyed. The dried matter may be afterwards fed into the furnace itself and consumed.—C. C. H.

Improvements in the Preparation of Materials for use in the Treatment of Sewage and Other Foul Liquids, in order to Purify them, and in the Method of Treating them, and in Apparatus for Use in their Treatment. W. B. Hallett, Goring. Eng. Pat. 12,382, Sept. 29, 1886. 8d.

THE sewage is first rendered alkaline and then treated with from 4 to 20grs. per gallon of the improved compound. This is prepared by grinding and mixing three parts by weight of commercial sulphate of alumina or iron, or both, with two parts of spent oil-shale, or other carbonaceous matter, or a carbonised mixture of clay, shale and tar. The sludge is settled out in tanks or in the improved apparatus described. This apparatus consists of a tall rectangular tank slightly larger at the bottom than at the top; a centre diaphragm divides one side from the other reaching nearly to the bottom, so that the treated sewage passes down to the bottom and rises again before flowing off at the upper part. The sludge collects at the bottom and is removed by lifting two large valves admitting it into an outlet chamber provided with a stop valve.—C. C. H.

Combining Disinfectants with Soda Crystals. R. L. Hickes, London. Eng. Pat. 6209, April 28, 1887. 4d.

A SATURATED solution of soda crystals is made in water at the boiling point. At the moment of crystallisation, on cooling, a mixture of diamylene, camphene, menthene, terebene, cymol and thymol, and sometimes phenol, is added.—C. C. H.

XVIII.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Porous Cells of Cork. M. Stein. Electrician, **19**, 245.

THE author succeeded in making porous cells of cork, which are very light and not easily broken. Finely powdered cork is made to a paste with water and a small quantity of naphthalene added, moulds are filled with this mixture and dried at a low temperature. The presence of naphthalene is said to prevent the formation of salt-crusts on the sides of the cells.—S. H.

The Electrolytic Reduction of Antimony with Recovery of the Sulphur in both Ore and Solvent. W. Borchers. Chem. Zeit. **11**, 1021—1022.

THE process is based on the electrolytic separation of the antimony from its solution in a liquid containing sodium sulphide, and is really an application on the large scale of the analytical method of Classen and Ludwig. Any antimony compound which is thus soluble may be employed, the presence of hydro- or poly-sulphides being immaterial. But the ratio of sodium to sulphur should be maintained at 1 : 1 ; for above this, any excess of the former causes an increase in electrical resistance, of the latter a separation of sulphur. A preponderance of Na S is advisable, as, although such a mixture as $Sb_2S_3+Na_2S+2NaHO$ contains the correct relation of sodium to sulphur, it is too unstable to be of practical use. Antimonite is most suitable for the process, very poor ores being available, owing to the ready solubility of the Sb_2S_3 in even dilute solutions of sodium sulphide. After extracting by Na_2S solution to a gravity of 12° B., about three per cent. (on the whole solution) of sodium chloride should be added to increase the conductivity of the liquid. The decomposing tanks may be of iron, and are thus available as cathodes, to increase the surface of which a concentric lining in metallic connection with them may be used, the anodes being inserted between, but insulated from them.

The anodes are of lead, the presence of the sulphur compounds in the electrolyte tending both to hinder the solution of the metal and to prevent the formation of dioxide. An intensity of 2 to 2½ volts per cell is required. The deposited antimony is either pulverulent or in shining scales. It is collected (the portion clinging to the anode being detached by steel brushes), washed first with water containing a little Na_2S, NaOH or NH_3, then with pure water, next in water slightly acidulated with HCl, and finally again with pure water; it may then be dried and fused with glass of antimony. The depositing solution may afterwards be made to yield the sodium chloride added, and also sodium thiosulphate. In an experiment with 9·62 kilos. of sodium sulphantimoniate, with 0·8 of sodium hydroxide, 2·437 out of a possible 2·440kilos. of antimony were recovered, the mother-liquor consisting of 2·4kilos. of NaHS, 1·2kilos. of Na_2S_2 and 1·5kilos. of $Na_2S_2O_3.5H_2O$. In another trial with 3·4kilos. of Sb_2S_3 and 7·2kilos. of Na_2S (crystallised) a loss of 5grms. of antimony on 2·4kilos. occurred, the residual liquid containing 1·3kilos. of NaHS, 1·2kilos. of Na_2S_2 and 1·6kilos. of $Na_2S_2O_3.5H_2O$. The explanation of the reactions at the anode and cathode respectively are :—

$$Sb_2S_3+3Na_2S+6H = Sb_2+6NaHS$$
$$6NaHS+3O = 3H_2O+3Na_2S_2.$$

The difference between this statement and the actual numbers obtained from the second experiment is to be ascribed to the imperfect circulation of the liquid in the cell, whence a higher degree of oxidation of one portion occurs before the hydrosulphide formed at the anode can reach the opposite pole. In the first experiment the reaction at the anode is supposed to be :—$2Na_3SbS_4+2NaOH+6H=Sb_2+2Na_2S_2+4NaHS+2H_2O$. These reactions are fully borne out by the experimental numbers and it would thus appear that the decomposition occurs through the electrolysis of 3 molecules of water for every 2 atoms of antimony in each case.

—W. G. M.

The Change Produced in the Retort Carbon when used as the Positive Electrode in the Electrolysis of Acids. H. Debray and Péchard. Compt. Rend. **105**, 27.

WHEN retort carbon is used in the electrolysis of acids the positive electrode is always more or less rapidly destroyed with the formation of a black, finely divided powder. The authors found the powder to contain 9—10 per cent. of oxygen, 8—10 per cent. of water and when nitric acid was electrolysed, nitrogen also. They regard this as a chemical rather than a mechanical action.—C. A. K.

Improvements in Secondary Batteries. W. J. S. Barber-Starkey, Bridgnorth. Eng. Pat. 8693, July 2, 1876. 4d.

IN those cells in which plates of lead and peroxide of lead in dilute sulphuric acid are usually employed a new electrolyte is used consisting of a solution of bisulphate of sodium or a mixture of bisulphate of sodium and dilute sulphuric acid. If the plates are coated with a white insoluble compound, carbonate or bicarbonate of soda, or a mixture of both, is added to the dilute acid. A solution of sulphate of sodium may be used.—B. T.

Improvements in Secondary Batteries. E. Andreoli, London. Eng. Pat. 12,595, Oct. 4, 1886. 6d.

TO increase the conductivity of the peroxide plates formed according to Eng. Pat. 8842, of 1886, the inventor employs thin metallic conductors of any suitable shape either in the mass or on the surface. These do not serve as supports, but to increase the discharge per plate and to utilise more fully the active material by collecting the current from all parts of it, thereby lessening the resistance. The conductors may be of any material that will not be acted on by the acid or cause local action with the peroxide.—E. T.

Improvements in Secondary Batteries. W. W. Beaumont, London. Eng. Pat. 12,818, Oct. 8, 1886. 8d.

PIECES of active material moulded into regular forms and preferably composed of Fitzgerald's "Lithanode," are arranged in regular or irregular order in moulds of suitable form for the electrodes and lead or lead alloy is either poured or forced into the interstices. This operation is performed under pressure to prevent blow holes forming and also to force the lead into every interstice. The active material may consist of a mixture of oxides of lead or partly of sulphates, or sulphites and water, sulphuric acid, steam, sulphate of ammonia or similar suitable materials.—B. T.

An Improvement in the Manufacture of Carbons for Electrical and Other Purposes. W. R. Johnston, Clanchattan, N.B. Eng. Pat. 13,648, Oct. 25, 1886. 4d.

PAPER pulp, which may be that made from textile or other fibre, or from straw, wood or other vegetable material, is moulded into the desired shape, subjected to pressure and carbonised in the usual way. To give greater cohesion the pulp is sometimes mixed with materials such as starch, sugar or tar.—B. T

Improvements in Obtaining Gold from Refractory Ores or other Substances. J. B. Hannay, Loch Long. Eng. Pat. 14,061, Nov. 2, 1886. 6d.

THE crushed ore is chlorinated either by electrolytic means or by the injection of liquefied chlorine; but in any case the premature precipitation of the gold by ferrous salts, produced *in situ*, is prevented by a solution of a soluble cyanide or sulphocyanide contained in an inner porous compartment, in which is placed the cathode of a comparatively feeble electric current: the anode being placed in the external chamber. The solution should be slightly alkaline and therefore commercial potassium cyanide may be employed.—W. G. M.

Improvements in Galvanic Batteries. T. Goodman, London. From C. Gassner, jun., Mainz, Germany. Eng. Pat. 16,810, Dec. 22, 1886. 4d.

Protoxide of zinc is thoroughly mixed with the exciting salts and plaster powder of a dry cell before water is added. The otherwise heavy and hard mass becomes porous and so facilitates the exchange of gas and lessens the polarisation and resistance of the cell. The inventor uses two parts of plaster to one of protoxide.—E. T.

Improvements in the Production of Aluminium and of Alloys of Aluminium and Copper by Electro Deposition. C. A. Burghardt and W. J. Twining, Manchester. Eng. Pat. 2602, Feb. 19, 1887. 6d.

To a solution containing copper and aluminium chlorides, from which excess of acid has been evaporated, sodium hydroxide is added to complete precipitation of copper hydroxide and re-solution of alumina. 16oz. of potassium cyanide per ounce of metal in solution is now added, and the liquid heated until the copper is dissolved. Half that quantity (8oz.) of potassium bicarbonate is added and the mixture boiled for about 24 hours. After filtration, if necessary, a small quantity of hydrocyanic acid is added, when the bath is ready for depositing a bright alloy of copper and aluminium at a temperature of 180° F. and with a platinum or aluminium bronze anode.—W. G. M.

Improvements in Primary Batteries. C. L. Tweedale, Crawshawbooth. Eng. Pat. 4648, March 29, 1887. 8d.

In this two-fluid battery the positive element consists of either lead, tin, copper, or alloys composed of these metals, and is immersed in any suitable acid or solution of an acid salt; when lead is employed the best results are obtained from a mixture of nitric and hydrochloric acids. The negative element consists of platinum or carbon and is immersed preferably in dilute nitro-sulphuric acid, but nitric alone or nitro-hydrochloric acid may be used. Arrangements are made for withdrawing the liquids from the two cells independently of one another.—B. T.

Improvements in Galvanic Batteries. J. Serson and J. O. Whitten, Boston, U.S.A. Eng. Pat. 10,217, July 21, 1887. 8d.

A cylindrical zinc rests in a circular channel in the bottom of the outer cell containing mercury. The porous cell contains a cylindrical carbon, within which are three small porous cells resting in sockets formed in the base of the large porous cell. The latter contains water, sulphuric acid, nitric acid, chromic acid and bichromate of potash, and of the small porous cells the first contains bichromate of potash, the second nitric acid, and the third sulphuric acid to reinforce the compound solution. The outer cell contains a solution (1:6) of sulphuric acid. The lid, which is held on by a cam, may have india-rubber rings on it to prevent spilling and mixing of the liquids.—B. T.

XIX.—PAPER, PASTEBOARD, Etc.

Improvements in the Manufacture of Paper to render same Antiseptic and Germ Proof. R. D. Sinclair and J. B. Brown, Glasgow. Eng. Pat. 12,217, Sept. 25, 1886. 4d.

Resorcinol, prepared by fusing galbanum resin with potassium hydrate, or from coal tar, is incorporated with the paper pulp in the proportion of one to two thousand; oil of Eucalyptus is sometimes added.—C. C. H.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Occurrence of Methyl Alcohol in the Vegetable Kingdom. H. Gutzeit. Annalen, **240**, 243—244.

It has been shown by Maquenne (this Journal, 1886, 317) that on distilling fresh plants with water the distillate contains methyl alcohol. The latter may already exist in the plant or it may be produced as a decomposition product during the process of distillation. The author states that the occurrence of alcohol in plants is no novelty. In 1875 he discovered its presence in the distillates from the fruits of the following plants:—*Heracleum giganteum*, *Pastinaca sativa L.* and *Anthriscus cerefolium Hoffm.*, whilst in 1879 he extracted ethyl compounds from heracleum fruits by means of pure ether. Having recently isolated methyl alcohol from *Acorus calamus L.*, in the course of an investigation on the constituents of the rhizome of this plant, the author concludes that methyl and ethyl alcohol exist in a free state in plants.—D. B.

Medico-chemical Notes. V. Meyer. Ber. **20**, 1725—1731.

1. *The Stability of Sublimate Solutions.*—Professor Angerer of Munich recommends the addition of common salt as a preventive against precipitation of sublimate solutions made without distilled water. The author finds that common salt, even in the proportion of 1 to 4, has not this property in tightly closed vessels and in corked vessels it has but a slight preservative action. On the other hand it has a considerable preservative action in open or loosely closed vessels.

2. *Physiological Action of Chlorinated Ethyl Sulphides.*—As the author has already shown, thiodiglycolchloride $CH_2Cl.CH_2.S.CH_2.CH_2Cl$ is a powerful poison and produces terrible blisters and ultimately necrosis when in contact with the skin. The effect of the monochlorinated compound has been tried with the following result:—A small quantity placed on a rabbit's ear produced inflammation but not so violent as the dichloride; after 48 hours the inflammation had gone down. No inflammation below the epidermis occurred. Rabbits in a confined space and subject to the vapours of the monochloride, died on the fourth day. The action of the non-chlorinated product is not poisonous. The poisonous action is therefore directly due to the presence of chlorine.—J. B. C.

Localisation and Recognition of Alkaloids in the Plants containing them. B. Errera. Bull. de la Soc. Roy. de Pharm. de Brux. **31**, 217.

Aconitine is contained in all parts of the *Aconitum napellus*, though not uniformly diffused. The greatest amount is found in the ovaries and in the extremity of the root—the so-called vegetation point. Considerable quantities are also contained in the other parts of the root, the blossom, and the seeds. The reaction with sulphuric acid and sugar can also be obtained in the case of the dry plant, provided the latter has been previously softened by soaking in luke-warm water.—W. S.

Notes on the Chemistry of Strophanthin. T. R. Fraser. Pharm. J. 1887, 69.

The active principle obtained by the author from strophanthus seeds, some years ago, by treating the alcoholic extract with ether, is found to be resolvable by acetate of lead into at least two bodies, one of which is an extremely active glucoside and the other an acid for which the name *Kombic acid* is suggested. The following is an outline of the process now recommended for the preparation of strophanthin:—The product obtained in the earlier process is dissolved in water, tannic acid added and the tannate digested with recently precipitated oxide of lead. This is extracted with rectified and proof spirit, the extract obtained dissolved in a small quantity of rectified spirit and the solution precipitated by ether. The precipitate is finally dissolved in weak alcohol and carbonic anhydride passed through this solution for several hours, by which means lead is completely got rid of. After filtration, the solution is evaporated at a low temperature and dried *in vacuo* over sulphuric acid. Strophanthin thus obtained, is imperfectly crystallised, neutral in reaction, intensely bitter, freely soluble in water, less so in rectified spirit and nearly insoluble in ether and chloroform. All the mineral and many organic acids resolve strophanthin, even in the cold, into glucose and a body which the author names strophanthidin.—W. E.

Tests for some Pharmaceutical Preparations recommended by the Committee of the German Pharmaceutical Society. Arch. Pharm. **25**, 653.

Tartaric Acid.—The aqueous solution (1 : 10) must not be altered by calcium sulphate, sulphuretted hydrogen or ammonium sulphide. Barium nitrate and ammonium oxalate must not produce an immediate turbidity *Lard.*—It should be white and nearly without smell. A boiled mixture of 2 parts of lard, 3 parts of caustic potash and 2 parts of water, should remain almost clear on the addition of 50 parts of water and 10 parts of alcohol. *Sulphuric Ether.*—Mixed with fifteen times its volume of water, it should remain clear. It should be kept protected from light, as the influence of the latter may conduce to the formation of aldehyde or hydrogen peroxide. *Acetic Ether.*—It frequently contains butyric ether and amyl-compounds, which are detected by steeping filter paper in the ether to be tested and allowing the latter to evaporate. The paper must not have the characteristic smell of the foreign ethers towards the end of the evaporation. *Codeïne.*—Dried at 100°C. it should lose 6 per cent. of its weight and should burn without residue. A solution of potassium ferricyanide, to which one drop of iron perchloride has been added, must not immediately turn blue on the addition of an aqueous codeïne solution acidified with 1cc. of hydrochloric acid. This test detects very small quantities of morphia. *Collodium.*—It is to be prepared by moistening one part of collodium wool with 7 parts of alcohol, adding 42 parts of ether and shaking repeatedly. The solution is allowed to subside and the supernatant liquor is drawn off. *Iron Lactate.*—On igniting, it should leave 27 per cent. of iron peroxide. Sugar is detected by boiling 30cc. of the solution (1 : 50), to which 3cc. of dilute sulphuric acid has been added, for some minutes and adding caustic soda solution in excess. The mass is filtered and the filtrate heated with 0·1grm. of potassium-sodium tartrate and some drops of copper sulphate solution should not give a precipitate of red cuprous oxide. *Iodoform.*—It is sometimes adulterated with picric acid, which is easily detected by shaking the crystals with water and filtering. The filtrate should be colourless.—S. H.

Antipyrine as a Substitute for Morphine for Subcutaneous Injections. Germain Seé. Compt. Rend. **105**, 103.

The dose for subcutaneous injections is 0·5grm. of antipyrine dissolved in an equal weight of water. The injection, which is effected just as in the case of morphine, produces a diminution of pain after first causing a pain which lasts for a few moments, and is unattended by the unpleasant secondary actions due to morphine. Antipyrin possesses a further healing power which morphine does not, and this in addition to its antiseptic action. The author has not met with any cases in which antipyrin cannot be substituted for morphine.—C. A. K.

Synthesis of Pilocarpine. Hardy and Calmels. Compt. Rend. **105**, 68.

Starting from β-pyridine ethylidene lactic acid, the authors prepared β-pyridine α-bromopropionic acid by treatment with PBr_3 dissolved in carbon bisulphide. The bromine substitution product was separated as the gold double salt $C_8H_8BrNO_2.AuBr_4H$ and this, when decomposed in presence of alcohol by sulphuretted hydrogen, yielded the free acid in a syrupy form. On dissolving the latter in a solution of trimethylamine and heating the whole in a closed tube to 150°, a product resulted from which a few drops of the alkaloid *pilocarpidine* were extracted by ether-alcohol. The methyliodide addition product of pilocarpidine was next prepared and this, on oxidisation with silver permanganate until all the iodine in the methyliodide had been precipitated, yielded pilocarpine, which remained in solution and which possessed all the physiological properties of the natural alkaloid.—C. A. K.

On the Secretion of the Araucaria. E. Heckel and F. Schlagdenhauffen. Compt. Rend. **105**, 359.

It is usually supposed that the secretions of the coniferæ consist of an essential oil and a resinous substance. The authors' experience shows that this is not the case for a large number of coniferæ, especially the araucaria group. Their secretion consists of resin, essential oil and a pure gum, which turns the plane of polarisation to the left, is oxidised by nitric acid to a mixture of mucic and oxalic acids and contains traces of glucose.—S. H.

Phenol-Cocaine. Viau. Nouv. Remèd. **87**, 192.

The author recommends phenol-cocaïne as a very efficient local anæsthetic in surgical dentistry. It is prepared by heating for a short time, two parts of cocaïne with one part of phenol.—S. H.

The Alkaloids of the Coca Leaves, O. Hesse. Pharm. Zeit. **32**, 407.

Stockmann supposes the amorphous cocaïne to be a solution of cocaïne in hygrin. The author's results do not support this, although he finds that hygrin may be formed during the decomposition of one or other of the coca-bases. The blue fluorescence of a dilute hydrochloric acid solution of hygrin was the test adopted for detecting its presence. The leaves were treated with ammonia, shaken with ether and the ethereal extract shaken with dilute hydrochloric acid, and it was found that with fresh, unbruised leaves, the acid solution did not show any fluorescence at first, but on standing the characteristic blue fluorescence gradually appeared, showing that hygrin is a decomposition product. Hygrin is precipitated from its acid solution by ammonia or caustic soda as a basic oil with a characteristic smell.

The author also separated an amorphous base, having the same empirical formula as cocaïne ($C_{17}H_{21}NO_4$) from a small leaved coca plant, to which he gives the name *Cocamin*. It is readily soluble in alcohol, ether, and chloroform, melts at 80° and is decomposed above 100°.—C. A. K.

Coriander Oil. R. Eck. Pharm. Zeit. **32**, 423.

Fifty kilos. of the dried seed extracted with direct steam yield on an average 550grms. of rectified oil. The oil gives a brown-red colouration when mixed with a drop of sulphuric acid on a watch glass; a bright red with nitric acid, which passes into lilac and blue on warming; and with a drop of tincture of iodine a green to dark green colour. All these colorations are destroyed on adding alcohol.—C. A. K.

The Alkaloid of Indian Hemp. E. Jahns. Arch. Pharm. **25**, 479.

The alkaloid supposed to exist in Indian hemp is, according to the author, simply choline. It exists in varying amounts from 0·05—0·1 per cent. Five kilos. of hemp were worked up, but there was not the least indication of the presence of any other alkaloid.

—C. A. K.

The Ethereal Oil of Black Pepper. L. A. Eberhardt. Arch. Pharm. **25**, 515.

The oil has the characteristic smell of pepper, is of a green colour, and at 15° has a sp. gr. of 0·8735. It is not miscible with alcohol (sp. gr. 0·830), but mixes readily

on addition of ether. Subjected to fractional distillation it yields a levro-rotatory terpene boiling at 169·5—171°, and having the sp. gr. 0·858 at 20°, together with higher boiling isomers. The fractions up to 180° are colourless, but above this temperature they are greenish to blue-green; above 310° a thick brown residue remains in which the presence of a phenol could not be proved.
—C. A. K.

Ueuhuba, the Seeds of Myristica Surinamensis. A. Tschirch. Arch. Pharm. **25**, 619.

THESE seeds contain 72·5 per cent. of fat, which is solid, of a yellow colour and melts at 36°. The fat fills the inside of the seeds, is in part amorphous and in part crystalline. The seeds, which morphologically resemble the ordinary musk seed, contain no starch but are specially characterised by the presence of large, regular and well-formed albumen crystalloids.—C. A. K.

Arbutin. W. Stoeder. Nieuw. Tijdsch. Pharm. Nederl. 1887, 176.

THE author obtained 1·6 per cent. of arbutin from the leaves of the strawberry tree (arbutus). He confirms the formula, $C_{25}H_{34}O_{14}$ and finds that on gentle warming with dilute sulphuric acid, it is decomposed into sugar, quinol (hydroquinone) and methyl quinol.—C. A. K.

A New American Vaselin. R. Gerstenberger. Pharm. Post. **20**, 462.

"SALVO PETROLIA" is the name given to a new vaselin which is sold in two forms—white and light coloured. The former possesses no smell at the ordinary temperature, melts at 35° and after melting has a slight smell of petroleum. Treated with sulphuric acid, it soon becomes brown and after ten minutes' standing, black. When melted and poured into a test tube it assumes a dirty white colour with a tinge of yellow on cooling. Its sp. gr. is 0·833.—C. A. K.

The Fatty Oil of Strophanthus Seeds. O. W. Fischer. Pharm. Post. **20**, 489.

IN thin layers the oil is of a greenish-yellow colour, and in thicker layers dark green with a red fluorescence by reflected light: it is a thick liquid at the ordinary temperature and possesses a narcotic smell due to the presence of a small quantity of an ethereal oil. This latter is removed by distillation with steam and may be extracted from the aqueous distillate by means of ether, which when distilled off leaves it behind as a colourless oil. The fatty oil has a sp. gr. of 0·9247 at 21°; it is only slightly soluble in boiling alcohol but dissolves readily in ether and chloroform. Nitric acid does not dissolve it but colours it emerald green and on warming the colour passes first to brown and then to yellow. The oil is readily saponified by caustic potash, and contains 92 per cent. of total fatty acids. Köttstorfer's test gave as a mean of two determinations 179·5, and Hübl's iodine test in two experiments, 95·3 and 95·9. The green colour of the oil is due to its containing chlorophyll.—C. A. K.

Acetphenetidine as an Antipyretic. E. Ghillany. Ztschr. österr Apoth. Ver. **25**, 339.

ACETPHENETIDINE, prepared by Hinsberg, has the formula $C_2H_5O.O.C_6H_4.NH.C_2H_3O$. It reduces the temperature gradually for 4—6 hours, when the maximum reduction of 2° is reached. In none of 50 cases in which it was employed were any unpleasant after-symptoms observed.—C. A. K.

Occurrence of Methyl Alcohol in the Calamus-Root. A. Geuther. Annalen, **240**, 109.

IN the course of an investigation of this substance, undertaken as a review of H. Thom's work (*Arch. Pharm.* **24**, 465; also this Journal, 1887, 560), the results of which are in the present publication shown to be erroneous, the author succeeded in isolating a quantity of a liquid sufficient for identification as methyl alcohol.
—C. F. C.

The Ethereal Oils of Allium Ursinum. F. W. Semmler. Annalen **241**, 149.

THE author summarises the results of his investigation as follows: (1) The oil consists chiefly of vinyl sulphide, containing, in addition, but in small proportion, a polysulphide of this radicle, a mercaptan, and an aldehyde. (2) The crude oil treated with metallic potassium yields directly pure vinyl sulphide of sp. gr. 0·9125 and boiling point 101°, the odour of which is similar to and yet distinct from that of allyl sulphide. (3) The corresponding oxide $(C_2H_3)_2O$ boils at 39°; it is obtained from the sulphide by treatment with dry silver oxide. (4) Moist silver oxide, on the other hand, determines oxidation, vinyl alcohol is the first product, and passing into the isomeric acetaldehyde, the oxidation to acetic acid is completed. (5) Vinyl sulphide is oxidised by nitric acid, permanganates and chromic acid, to carbonic, oxalic and sulphuric acids, no sulphones being formed. (6) The sulphide forms crystalline compounds with $HgCl_2$, $PtCl_4$ and $AgNO_3$, according to the following equations respectively:—

$$(7)\ 2(C_2H_3)_2S + 2HgCl_2 = 2C_2H_3Cl.HgCl_2(C_2H_3)_2SHgS.$$

$$(8)\ 3(C_2H_3)_2S + 2PtCl_4 = 4C_2H_3Cl.Pt.Cl_4(C_2H_3)_2S.PtS_2.$$

$$(9)\ (C_2H_3)_2S + 2AgNO_3 = (C_2H_3)_2S.2AgNO_3.$$

(10) The sulphide absorbs the halogens and the halogen hydracids. With bromine it combines to form the compound $(C_2H_3Br_2)_2SBr_2$. (11) By the action of potassium sulphocyanide upon the mercury compound (7) vinyl mustard oil is formed C_2H NCS.—C. F. C.

Andromedotoxin, the Poisonous Principle of the Ericaceæ. H. G. de Zaayer. Archiv. f. Pbysiol. **40**, 480.

PLUGGE has shown that andromedotoxin is not only the poisonous principle of *Andromedas*, but very probably also of all the poisonous ericaceæ. The author has extracted this poison in considerable quantity from *Rhododendron ponticum*. Pure andromedotoxin forms small white crystalline needles, which melt and begin to decompose at 228°—229°. It is not altered by continued heating at 100°. It dissolves in alcohol, chloroform, ether and benzene, and is three times more soluble in cold than in boiling water. When dissolved in water or alcohol the solution is levro-rotatory, while the chloroform solution turns the plane of polarisation to the right. It belongs to the indifferent, non-nitrogenous bodies; its solutions in indifferent liquids have an alkaline reaction and are not precipitated by any of the general precipitants for alkaloids. It is fairly stable, is not decomposed by acetic acid on boiling and only decomposed by strong solutions of oxalic or tartaric acid after boiling for a long time. It is not precipitated from its solutions by metallic salts, nor does it reduce Fehling's solution. Concentrated sulphuric acid dissolves it with a dark red-brown colour. When evaporated with dilute sulphuric, hydrochloric or phosphoric acids, colorations varying from rose-red to violet-red are obtained; these reactions are all very delicate. The author assigns the formula $C_{31}H_{51}O_{10}$ to the pure substance.—C. A. K.

Improvements in Means for the Manufacture or Production of Ozone. A. Brin, London, and L. Q. Brin, Paris. Eng. Pat. 11,846, Sept. 17, 1886. 8d.

THE patentees produce ozone commercially from air or oxygen by causing electric sparks to pass between layers or masses of conducting material so disposed as to present a large surface. The conducting material may consist of granular plumbago, iron, zinc or copper filings, or dust shot. Drawings of the apparatus employed accompany the specification.—E. J. B.

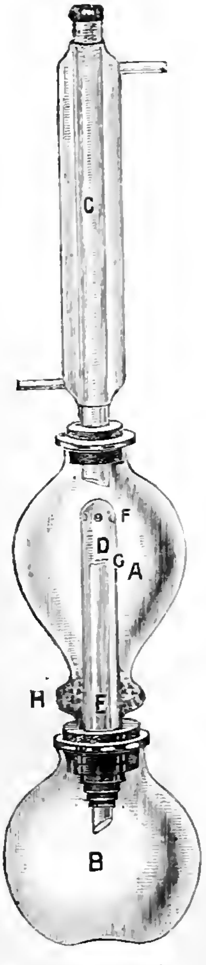
A Dental Anodyne or Local Anæsthetic. C. T. Arnold, London. From C. W. Arnold, Florida, U.S.A. Eng. Pat. 7061, May 18, 1887.

CHEMICALLY-PURE acetic acid is neutralised with ammonium carbonate and the mixture saturated with salicylic acid. The whole is then filtered and treated with "cocoaine hydrochloride." This compound is used for preventing or relieving the pain in sensitive dentine during the process of preparing the cavity of the tooth for the purpose of filling it. It also acts as disinfectant and deodoriser for preventing septic action and lessening the liability to trouble usually following a dental operation.—D. B.

XXII.—ANALYTICAL CHEMISTRY.

A New Extractor, especially suitable for Experimental Researches. Dr. R. Rempel. Chem. Zeit. **11**, 936.

THE author, finding Soxhlet's and Drechsel's apparatus unsatisfactory for the purposes for which he required them, has devised an extractor which may be made of size sufficient to treat 100grms. or more of material at one operation. In the subjoined figure, A is the extractor with a lower bulb H; it is connected by corks with an upright condenser C above and with a flask B, to contain the solvent, beneath. Within A and maintained in place by an air-tight cork on which it rests, is the tube D, which has openings F above into A and also openings into the bulb H of the extractor; through the cork is passed the tube E. This innermost tube is cut off at an angle beneath and has a notch G at the top of the longest side. The mouth of the condenser is closed by a plug of cotton wool. When in use the bulb H is filled with cotton wool or other filtering medium and the matter to be treated is placed above. The vapour of the solvent passes from B, through the tube E and the holes F, into the extractor A and thence into the condenser, where it becomes liquefied. The liquid percolating through the substance under extraction becomes more or less saturated and finds its way through the lower perforations in D; and as more liquid condenses, it gradually rises between the two tubes until the notch G is reached, whence it finally trickles down the walls of the tube E into the flask. The height of the solution in the extractor may be regulated by adjusting the sliding tube E; or, if the material treated permits only a very slow filtration, this tube may even be removed without fear. The extraction ended, the vessel A is emptied, the tube E then raised as high as possible and the liquid still left in B distilled into A, whence it is subsequently removed. The greater part of the solvent is thus recovered without the aid of any special distilling arrangement.—W. G. M.

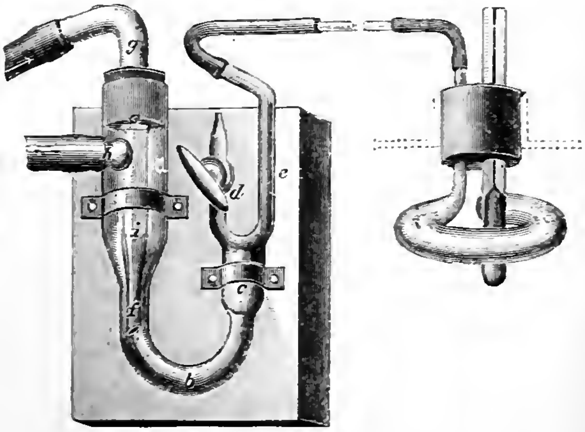


Orsat's Apparatus. Chem. Zeit. **11**. 989—990.

IN order to allow the copper spirals and capillary tubes in this apparatus to be readily removed when required, as well as to facilitate the washing out of the apparatus, C. Heintz has fitted the vessel A with a well-ground and air-tight stopper, thus avoiding the renewal of the vessel due to the spirals getting burned or to the breaking of the capillary tubes.—C. A. K.

A Practical Thermostat. L. Rügheimer. Ber. **20**. 1280—1284.

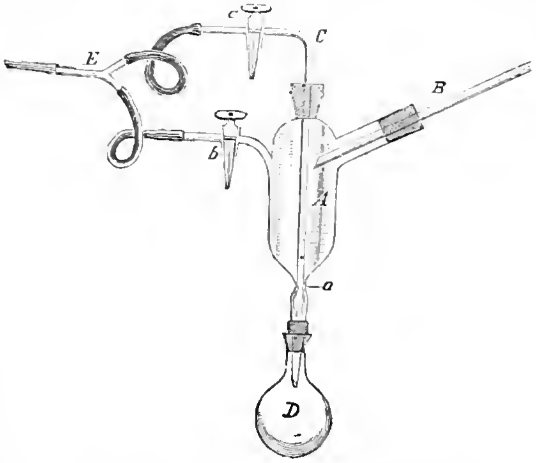
THE apparatus consists of a glass tube *a* with thick walls (see figure) to which a side tube *h* is attached and also a narrower U-tube *b* opening into a wider tube *c*. The latter terminates on one side in a tube and simple glass stop-cock *d*, on the other side in a narrow thick-walled tube *e* with a knee-shaped bend. The tube *g* is fixed in *a* by means of a cork and is drawn out towards *f* and cut off at an angle. The tube *g* is also perforated at *i*. The mercury placed in *b* is just in contact with the open end of *f*. When the gas tap is open, gas passes through *g* and *f* and then through *h* to the heating apparatus. If the tap *d* is now closed and the temperature



of the air bath raised, the mercury will rise and partly close the aperture at *f*. The total extinction of the flame is prevented by the hole at *i*, which supplies a constant stream of gas to the flame. The apparatus used in connection with an air-bath for 8 sealed tubes has the following dimensions: *f* has a diameter of 5mm. and walls 0 75mm. thick, and *b* a diameter of 8½mm. The mode in which the apparatus is regulated requires no detailed description. The tap *d* is gradually closed as the required temperature is reached; or better still the tap is closed completely several degrees below the point required, the temperature allowed to become constant, the tap again opened and quickly closed and this operation repeated once or twice.—J. B. C.

Apparatus for Fractional Distillation under reduced Pressure. L. Meyer. Ber. **20**, 1834—1836.

THE vessel A is attached to the end of the condenser B. In the upper end of A, which is 16mm. wide, a glass tube is fitted through a cork. The lower end of this tube is cut off at an angle, and is well ground into the narrow part of A at *a*. Below *a*, the lower end of A again widens and is then drawn out conically and cut off at an angle. To this conical piece the receiver D is attached by a well-fitting cork. The tube C is bent above A at right angles and on the horizontal portion a three-way glass cock *c* is fitted. A similar cock *b* is attached to the side of A. A simple tap may be substituted for the latter; a three-way tap is preferable in case the liquid should froth over. In order to use the apparatus, the two taps *b* and *c* are attached by strong narrow indiarubber tubing (1—2mm. inside diameter, 3—4mm. thick) to a T piece E, and this is connected with a manometer and water-jet aspirator. It is convenient, in case the liquid should run back, to insert a large empty wash bottle between E and the pump. The tube C is raised by a gentle upward turn so that A and D are in connection, and both taps turned, as in the figure, so that both are in connection with the pump. If a fraction of the distillate is to be separated, the tube C is pressed down, which shuts off D from A. In order to remove D the tap *c* is so turned that air enters through the tail of the tap and enters D through C. When D has been emptied or filled, *c* is slowly turned through 90° so that it is again in connection with the pump. The small quantity of air introduced produces a very slight change of pressure. When D has been again evacuated, by raising *c* the liquid in A is allowed to flow into D. The author recommends cork and not indiarubber stoppers.—J. B. C.



Laboratory Apparatus for Fractional Distillation. P. Monnet. Monit. Scient. 4 Sér. **1**, 335.

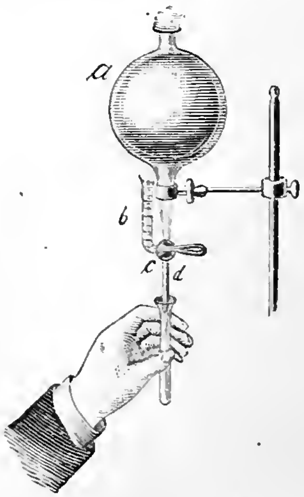
THE tube D, which serves as the dephlegmator, is 0·35—0·4m. high and has an internal diameter of 28—35mm., narrowed to 5mm. at the bottom to allow of its being fitted into the stopper of the flask B. It is filled with lead shot or, if acids are distilled, with pieces of glass or flint. For ordinary use lead shot No. 4 is used for the lower half and No. 6 for the upper half, the two being separated by a piece of copper gauze. In the case of very volatile substances, finer shot is employed and the length of the tube increased. A funnel with an upturned edge is inserted above the narrowed portion of the tube to support the shot. I is the tubulure leading to the condenser and H the thermometer which is fixed just above the top of the lead shot.

300cc. of a mixture of equal parts of water and alcohol yielded the greater part of the alcohol, on distilling, of a strength of 95%, and with a mixture of aniline and toluidine the author obtained nearly two-thirds of the aniline in a pure state after three distillations.

—C. A. K.

Apparatus for Measuring out Definite Quantities of Nutritive Solutions in Bacteriological Investigations. H. Treskow. Rep. Anal. Chem. **7**, 505—506.

THE construction of this apparatus, which is made of glass, will be readily understood from the accompanying diagram. *a* is the vessel containing the nutritive solution, *b* a graduated cylinder, *c* a cock with a right angled aperture drilled in it so that there may be either a passage from *b* to *a* or from *b* to *d*, which is the outlet tube; *a* and *b* are preferably closed by plugs of cotton wool. Any desired quantity of the solution can thus be rapidly measured into a test tube without any risk of introducing micro-organisms as would be the case if a pipette were used.—E. E. B.



Purification of Sulphuretted Hydrogen from Arseniuretted Hydrogen. O. Jacobsen. Ber. **20**, 1999—2001.

THE author passes H_2S gas, which has been completely dried, over solid iodine. This process is based upon the fact that AsH_3 readily combines with iodine to form AsI_3 and HI, whereas H_2S is not acted upon by the solid iodine. 2—3grms. of iodine suffice, and should be spread in layers between plugs of glass wool in a tube 30—40cm. long. The gas is then passed into water, when any iodine vapour remains dissolved in the water as hydriodic acid.—J. B. C.

Detection of Nitrogen Compounds in Seleniferous Sulphuric Acid. G. Lunge. Ber. **20**, 2031—2033.

SULPHURIC ACID containing selenium gives no reaction with diphenylamine, but on the addition of a layer of water the blue colouration is formed just as in the case of the nitrogen acids. With sulphate of iron solution the brown ring is also obtained, but this is only intensified on warming, due to the reduction of the selenium. From the above it follows that neither diphenylamine nor ferrous salts can be used for the detection of nitric acid in sulphuric acid containing selenium. Neither can indigo be used. Brucine gives, however, no reaction with selenious acid and can therefore be used in detecting nitrogen acids in concentrated sulphuric acid.
—J. B. C.

Notes on the Logwood Test for Alum in Bread, etc. W. C. Young. Analyst **12**, 145—147.

FURTHER experiments have led the author to modify the opinions expressed in a former paper. He finds, however, that aluminium phosphate is *slightly* soluble in cold acetic acid, although it is reprecipitated on boiling. The alumina naturally present in flour is *combined* with the gluten. Alumina would be detected in bread by the logwood test if present either as hydrate or phosphate, and the author now considers that this test is invariably efficient in detecting alum added to bread.—E. E. B.

Thomas Slag. J. H. Vogel. Rep. Anal. Chem. **7**, 469—477.

IN connection with the valuation of basic slag according to the fineness of the ground product (see this Journal, 1887, 46), it has been suggested that those portions which pulverise with facility contain phosphoric acid in a more useful form than the phosphoric acid of the remaining portions. The author has investigated this subject and finds, as many others do, that the percentage of phosphoric acid is higher in the fine than in the coarser portions of the ground slag and intermediate in the commercial product. Collateral experiments with these three forms of the slag indicate that on digestion with hydrochloric acid or with ammonium citrate they always yield phosphoric acid in the following order:—Most from the fine, least from the coarse, with the original commercial ground slag intermediate. With hydrochloric acid of different dilutions up to 1 : 8, the quantity of phosphoric acid dissolved increases with the dilution. The author is perfecting a method of analysis based on this fact. Taking all things into consideration, the author concludes that the phosphoric acid exists in the same forms in both the fine and coarse portions of the ground slag; and that the low percentage in the coarse stuff is due to the higher percentage of iron it contains.

The author recommends the following method of decomposing the slag in preference to Brunnemann's (see this Journal, 1887, 304); it is quicker and yields results within less than 0·1 per cent. from Brunnemann's. Five grams of slag are digested in a half-litre flask, with 100cc. of strong hydrochloric acid and 20cc. of concentrated nitric acid for half-an-hour on a water-bath; when cool the flask is filled up to the mark and the phosphoric acid determined in 50cc. by the molybdate method.

By fusing the slag with potash, extracting with hot water and digesting with ammonium carbonate, a constant quantity of phosphoric acid is always found in the solution, which invariably coincides with the quantity extracted by ammonium citrate.—D. A. L.

Determination of Titanic Acid. L. Levy. Pharm. Chim. **16**, 56.

To determine titanic acid in presence of alkalis or the oxides of magnesium, zinc, aluminium or copper, the substance is fused with five times its weight of potassium bisulphate, the melt extracted with water (if necessary with addition of sulphuric acid) and the liquid neutralised with caustic potash or ammonia. Sulphuric acid is then added to the extent of 0·5 per cent. by volume of the total solution and the whole boiled for six hours, water being added from time to time. The precipitated acid is ignited and weighed.—C. A. K.

The Reactions of Vanadium and their Application to Chemical Analysis. A. Carnot. Compt. Rend. **104**, 1850.

URANIUM SALTS precipitate vanadic acid, both from an ammoniacal solution and from a solution slightly acidified with acetic acid, and this reaction can be employed for its determination. The solution of vanadic acid is, if acid, very nearly neutralised with ammonia, a few grammes of ammonium acetate added, then an excess of uranium acetate and the whole heated to boiling, when a yellow precipitate is formed. To ensure the presence of an excess of uranium acetate a drop of the solution is tested with potassium ferrocyanide. The precipitate is filtered, washed and dried. Its composition is $V_2O_5.2UO_3(NH_4)_2O.H_2O$. This is heated to redness, together with the filter ash, and the resulting compound, $V_2O_5.2UO_3$ weighed. Vanadic acid can be determined by this method in presence of the alkalis, alkaline earths and of most of the metallic oxides whose acetates are not decomposed by boiling. The method is especially useful in separating vanadic acid from manganese, zinc and copper, but cannot be employed to separate it from the acids of arsenic or phosphorus.

A second method of determining vanadic acid depends upon the formation of an insoluble compound with manganese monoxide. A slight excess of ammonium chloride and ammonia is first added to the vanadium solution. The solution is then heated to boiling in a strong flask, when the manganese chloride or sulphate is added, mixed with ammonium chloride. The boiling is continued for 2—3 minutes, the flask corked and placed in cold water until the precipitate settles, after which the latter is filtered off and washed. It should be yellow brown in colour and become lighter on drying. It is finally ignited and weighed as $V_2O_5.2MnO$, which has a red-brown colour. By this reaction vanadic acid can be completely separated from molybdic acid. The filtrate from the above precipitate is treated with ammonium sulphide to remove the manganese and then molybdenum (if present) is precipitated as sulphide on the addition of hydrochloric acid. Phosphoric, arsenic and tungstic acids cannot be separated from vanadic acid by this method. The formation of the above precipitate also serves as a convenient means for isolating vanadium from alkaline or ammoniacal solutions. The manganese vanadate is heated with sulphur in a slow current of sulphuretted hydrogen and then treated with dilute hydrochloric acid (1 : 20), when the manganese sulphide is readily dissolved, while the sulphide of vanadium remains behind.—C. A. K.

Nitrates and Nitrites (II.). A Percy Smith. Analyst, **12**, 152—153.

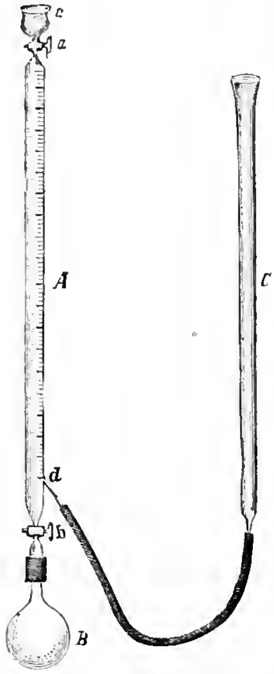
IN using the naphthylamine test, water must be prepared quite nitrogen-free by treating it with a copper-zinc couple for *at least* a week, rendering alkaline and distilling, rejecting any portion containing ammonia. The naphthylamine hydrochloride must be almost colourless, so it is advisable to keep animal charcoal in the bottle with it. It is best to perform the test by evaporating 100cc. *just* to dryness, adding ten drops of phenolsulphonic acid, then 1cc. of water, three drops of strong sulphuric acid, diluting, adding excess of ammonia and finally making up to 100cc. This reagent is better than *m*-phenylene diamine for ascertaining when all nitrites have been reduced by the copper-zinc couple, and the author prefers to use a surface of at least 8 sq. in. of zinc for 100cc. of water.—E. E. B.

Paraffin as a Preventive against Frothing during Distillation. H. Kunz. Arch. Pharm. **25**, 632.

Paraffin acts very effectually in preventing the frothing that generally occurs in decomposing ammonium salts by lime or magnesia. Two to three grms. are sufficient for an Erlenmeyer flask of 800cc. capacity, and containing 200—300cc. of solution.—C. A. K.

Estimation of Metallic Iron in Slag. G. Neumann. Zeits. Anal. Chem. **26**, 530—534.

The two methods at present in use for the estimation of metallic iron, mixed with iron compounds, are:—(*a*) Digestion with $HgCl_2$, and titration of the ferrous chloride produced, with $KMnO_4$; (*b*) Digestion with $CuSO_4$, weighing the separated copper or titration of the residual $CuSO_4$. The first method is liable to give too high results, the second, though very exact, cannot be employed when other bodies which decompose $CuSO_4$ are present; both methods require a great expenditure of time. The method employed by the author, whilst quite as exact as the above, has the advantage of being more rapid and generally applicable. The process consists in measuring the hydrogen evolved when the slag is treated with acid; this can be effected in a Lunge's nitrometer, but more conveniently with the apparatus figured. The flask B of 50—100cc. capacity, containing the material and nearly filled with water, is connected by indiarubber tubing to the graduated tube A of about 80cc. capacity and 1cm. wide. Water is poured through the tube C into B till the cock *b* is filled. The latter is now closed, and the cock *a* being open, the tube A is filled with acid through C. After closing *a*, *b* is opened and the acid allowed to mix with the water in the flask. On warming the hydrogen is given off, collects in A, and after the apparatus has cooled, it is measured and its volume corrected for temperature and pressure. If the hydrogen evolved contains CO_2 or H_2S, they can be removed by allowing some caustic potash to run in from the funnel *c*. The apparatus is also very serviceable for the estimation of metallic zinc in zinc dust or of CO_2 in carbonates.
—A. G. G.



On the Estimation of Phosphoric Acid in Thomas Slag. Dr. G. Kennepohl. Chem. Zeit. **11**, 1089.

The ready solubility of slag phosphates in moderately concentrated hydrochloric acid would have long since caused this method of extraction to become general in analysis, but that it was not clear whether it would be advisable thus to leave out of account the phosphorus existing in the slag as phosphide. Jensch, it is true, has shown (this Journal, 1886, 451) that iron phosphide is rapidly oxidised in garden soils, but this does not prove an equality between the phosphorus present as phosphide and that as phosphate. However, the author confirms the experiments of Jensch and Klein (this Journal, 1886, 451 and 502) as to the practical non-occurrence of iron phosphide in normal slags, and recommends the digestion of the phosphates for half-an-hour with strong hydrochloric acid, in which time the extraction should be absolutely complete. He has used the following method in the Darmstadt laboratory during the last two years:—10grms. of slag are introduced into a 500cc. flask, moistened with alcohol to prevent adhesion and heated in a water-bath for at least half-an-hour with 40cc. of HCl (1·12 sp. gr.) and 40cc. of water. After cooling, the flask is filled to the graduation mark and the solution filtered; 25cc. of the filtrate are then, after an addition of ammonium nitrate, precipitated directly with molybdate solution (without previous separation of silica), heated to 80° for 15 minutes, cooled, filtered, the precipitate washed with water containing 3 per cent. of nitric acid, dissolved in a 2½ per cent. ammonia solution and finally precipitated with magnesia mixture. The presence of the nitric acid in the wash-water for the phospho-molybdate precipitate is especially necessary in the presence of much iron, since a portion of the latter will otherwise remain and will contaminate the magnesium phosphate. In all the analyses made to test this process the magnesium precipitate after ignition was examined carefully, but in no case was any silica found, although no special precautions had been taken to ensure its exclusion. This is owing to the ready solubility of ammonium silicomolybdate. Where, however, a portion of the silica has become converted into the silicon-molybdenum salt, it may be readily removed by washing, the yellow colour of the wash-water being an indication of its presence. If the presence of ferrous salts should tend to cause the separation of molybdic oxide, which dissolves but slowly in ammonia, an addition of nitric acid or bromine, before introducing the molybdate solution, will ensure the production of a precipitate instantaneously soluble in the ammonia.—W. G. M.

Abnormal Ether Explosion. Ed. Schär. Arch. Pharm. **25**, 623.

The ether used was from a stock bottle which had been kept for many years; it was used for the estimation of fat in "coprah" and exploded while being evaporated in a platinum dish on an iron plate. It also did so with fats other than coprah. Analysis showed that the ether in question contained an extremely high percentage of H_2O_2 (over 5 per cent.), to which the author attributes the violent decomposition, it being favoured by the presence of the acids which are formed—viz., acetic and formic.—W. E.

A Note on Pettenkofer's Gallic Acid Reaction. F. Mylius. Zeits. f. Physiol. Chem. **11**, 492.

The author points out that this greatly depends upon the action of furfurol. If one drop of furfurol be dissolved in 10cc. of water, one drop of the solution is sufficient to colour a mixture of cholic acid, water and sulphuric acid blood-red. The substance which gives rise to the reaction is of itself apparently colourless and acid in property. It can be extracted by ether from the acid solution; 0·000,025grm. of furfurol can be detected by this cholic acid reaction. There are other substances which give a similar reaction with furfurol and sulphuric acid—viz., isopropylalcohol, isobutylalcohol, allylalcohol, trimethylcarbinol, dimethylethylcarbinol, amylalcohol, oleic acid, petroleum; the following do not give the reaction: ethylalcohol, propylalcohol, caprylalcohol, acetic acid, acrolein, benzene. Probably the alcohols do not in themselves enter into combination with furfurol, but the decomposition products by the action of the sulphuric acid.—W. E.

A Test for Linseed Oil and Linseed-oil Varnish. Ed. Hahn. Pharm. Zeit. **32**, 449.

THE readiest means of distinguishing these is by the action of lime water which, when mixed in equal proportions, gives a yellow permanent emulsion with linseed oil but not with linseed-oil varnish. Bleached linseed-oil varnish does not react like the unbleached but gives a pure white emulsion.—W. E.

Examination of Raw Sugar for Sulphurous Acid. Deutsche Zuckerind. **12**, 939.

ACCORDING to Davidson, 1·5—2cc. of cold, very dilute starch solution is poured over 1—1·5grm. of the sugar and as soon as the greater part of the sugar is dissolved a few drops of iodic acid are cautiously allowed to flow over the surface of the sugar solution. In the presence of sulphurous or hyposulphurous acid there immediately appears at the point of contact a blue ring. Second-rate products, as molasses, do not give this reaction, owing to the presence of reducing agents. To estimate the amount of SO_2, 10grms. of sugar are dissolved in cold water free from air, neutralised with H_2SO_4, a few drops of starch solution added and titrated with a centi-normal iodine solution until the blue colour no longer disappears. Ordinary sugars mostly require 0·3cc. of iodine solution, while some sugars as much as 9·8cc. equivalent to 0·03 per cent. of SO_2.—W. E.

Detection of "Fahlberg's Saccharin." C. Schmitt. Rep. Anal. Chem. **7**, 437—441.

THE tests for Fahlberg's saccharin (orthosulphaminebenzoic acid) depending on the formation of ammonia or the alkaline sulphides, are scarcely of sufficient delicacy or convenience for the detection of minute quantities, as, for instance, in wine. The following, based on the formation of salicylic acid during the fusion of saccharin with alkalis, is recommended where salicylic acid is not already present in quantities sufficient to impair the delicacy of the reaction. The wine is rendered strongly acid and 100cc. are shaken three times successively with 50cc. of a mixture of equal volumes of ether and light petroleum. The united extracts are evaporated after the addition of some caustic soda and the residue is heated at 250° for half-an-hour with 0·5 or 1grm. of solid caustic soda. The fused mass is dissolved in water and the salicylic acid separated and detected in the usual manner. In this manner 0·005 per cent. of saccharin, or even less, may be detected. The mixture of equal volumes of ether and light petroleum, an excellent solvent for saccharin, does not dissolve tannin and such like substances, which also form salicylic acid when fused with alkalis and would interfere with the test if they were extracted. Potash cannot be used for the fusion in place of soda.

—D. A. L.

Colour Reaction for Chloral Camphor. Haarst. Nieuw. Tijdsch. Pharm. Nederl. 1887, 179.

BY adding a trace of hydrochloric acid and a few drops of peppermint oil to chloral camphor, a red coloration results, which on warming, gradually passes into blue-violet. On diluting with alcohol or ether the liquid first becomes dark-blue, then blue-green and finally chlorophyll green with a blood-red fluorescence.—C. A. K.

The Carbamides and their Reaction with Nitric Acid. P. N. Franchimont. Rec. des. Trav. Chim. des Pays-Bas, 1887, 213.

THE author has already shown that carbamide and its methyl derivatives are readily decomposed at ordinary temperatures by nitric acid, with evolution of nitrous oxide. He has now examined other urea derivatives, especially those in which hydrogen is replaced by an acid residue and is led to the conclusion that, if the urea residue forms a closed chain with the residue of a mono or dibasic acid, it no longer behaves as an amide towards nitric acid, with a decomposition similar to that quoted above. A further study of these reactions showed that if carbamide forms a closed chain with a chain of two or three carbon atoms linked to hydrogen or oxygen, whether saturated or not, the resulting urea derivative is not decomposed by nitric acid at normal temperatures; if carbamide forms a closed ring with one carbon atom, nitric acid produces an unstable nitro-derivative which decomposes into a nitro-hydrocarbon and urea, the latter of which then suffers decomposition as explained. Uric acid is so broken up by nitric acid at common temperatures into carbon dioxide and nitrous oxide, as to show that one molecule of urea corresponds to one molecule of uric acid, though this does not, at first sight, agree with Medicus' formula for uric acid.—W. G. M.

The Determination of Certain Salts in Soap. F. M. Horn. Zeits. f. d. Chem. Ind. **16**, 85.

THE usual process of estimating the sulphate, chloride and carbonate of sodium or potassium in soap by extracting the soap with absolute alcohol and testing the residue, leads to wrong results, as absolute alcohol of commerce dissolves not inconsiderable quantities of those salts. Furthermore, the high percentage of water in soaps dilutes the alcohol, whereby salts go into solution in the alcoholic extract, which amount is always neglected. The author recommends to dissolve soap in water, separate the fat with nitric acid and determine the chlorine in the filtrate with silver nitrate. For estimating sodium or potassium carbonate and sulphate, the soap must be dried for a long time at 30° to 40° C. and afterwards at 110° to 120° C. The dry soap is then treated with absolute alcohol, filtered, washed, and the residue on the filter taken up with boiling water; one portion is titrated with standard acid, while another portion is retained for the estimation of sodium or potassium sulphate. Better still is a direct determination of the carbonic acid. Below are the results of two analyses, performed by the old (I.) and the author's (II.) process:—

	H_2O	NaCl	Na_2CO_3	Na_2SO_4	
Glycerine Soap	35·7	3·86	2·01	0·73	I.
Cocoa-nut-oil Soap	55·4	4·58	1·66	0·61	
Glycerine Soap	35·7	5·06	3·96	1·25	II.
Cocoa-nut-oil Soap	55·4	9·50	3·35	1·23	

—S. H.

Examination of Cane Sugar mixed with other Optically Active Substances by the Polarimeter, both before and after Inversion, and employing Clerget's Formula. W. Gautenberg. Chem. Zeit. **11**, 953.

DARK-COLOURED syrups and molasses may be decolorised by lead acetate without any prejudicial effect in the resulting measurements by the polarimeter. The product must be decolorised before inversion, then the lead precipitated by hydrochloric acid and an excess of acid added to effect the inversion. The weighed quantity of molasses is dissolved in water, decolorised with acetate of lead (if necessary with tannin), the solution made up to 100cc., filtered and examined in the polarimeter. 50cc. of the filtrate are next placed in a 100cc. flask, an excess of hydrochloric acid added and the flask warmed in the water-bath for not more than 15 minutes to 66—68° C. It is important not to exceed either the time of warming or the temperature and the flask should be placed inside the water-bath, not on a metal ring. After heating, the flask is cooled as quickly as possible to the temperature of the room, filled up to the 100cc. mark with water, allowed to stand at least 10 minutes and then the levro-rotatory power of the solution determined. This factor multiplied by two and corrected for temperature is introduced into Clerget's formula as the value for the inverted solution.—C. A. K.

Estimation of Rosin in Beeswax. F. M. Horn. Rep. Anal. Chem. **7**, 503—504.

A SAMPLE of bees-wax known to be impure was examined by determining the amount of alkali required to combine with the free fatty acid, the total alkali to effect complete saponification, the amount of matter extracted by ether and lastly, the ratio of the ether extract to the amount of alkali required to combine with the free fatty acid. Compared with the figures obtained with genuine beeswax, these results showed that stearic acid, tallow and rosin might be present. A glycerin test by Benedikt and Zsigmondy's process proved tallow, etc., to be absent and then from the ether extract no stearic acid could have been present. Rosin was found by Donath's test, which consists in boiling with nitric acid and adding first water and afterwards ammonia, when a blood-red colour is produced. The percentage of rosin (R) could then be calculated from the formula—

$R = \frac{100\ (A - a)}{(r - a)}$ where A, a and r were the amounts of alkali required to combine with the free acid in the mixture, in pure beeswax (20) and in pure rosin (146) respectively.—E. E. B.

Estimation of Extract of Conium. A. Kremel. Pharm. Post. **20**, 521.

To estimate the amount of coniine, 7·5grms. of extract are dissolved in 10—15cc. of water and the solution gradually brought up to 150cc. with 95 per cent. alcohol. To the solution placed in a cylinder 10grms. of freshly-slaked lime are added, the cylinder corked, the whole shaken and set aside twenty-four hours, then filtered. To the filtrate 1grm. of tartaric acid is added and the precipitated tartrate of lime filtered off: 100cc. of the filtrate (= 5grms. extract) are freed from alcohol by heating on a water-bath after the addition of 25cc. of water. After cooling, the aqueous solution is filtered, washed and the acid liquid exhausted with ether. After the removal of the ether the residue is rendered alkaline with KHO and then shaken with ether, which removes the conine. To the ethereal extract an equal volume of absolute alcohol and 25cc. of centi-normal HCl are added and the solution is titrated back with centi-normal NaHO, litmus being used as the indicator.

—W. E.

Determination of Sugar in Beet. Burkhard. Neue Ztschr. Zuckerind, **19**, 30.

THE author states that accurate and concordant results are obtained by the Siekel-Soxhlet apparatus, by that of Scheibler (both the old and new form) and by the Rapp-Degener method, provided the necessary conditions are carefully fulfilled. It is best to digest 51·2grms. of the beet with alcohol in the usual form of flask, with a capacity of 201·2cc., add 10—15 drops of acetate of lead and heat on the water-bath to 75° for three-quarters of an hour. In using Scheibler's apparatus A the time for extraction should be extended to one hour. Scheibler's apparatus B (capacity of flask 200cc.) is specially recommended.—C. A. K.

New Books.

THE EXTRA PHARMACOPŒIA, with the Additions introduced into the British Pharmacopœia, 1885. By WILLIAM MARTINDALE, F.C.S., etc. Medical References and a Therapeutic Index of Diseases and Symptoms, by W. WYNN WESTCOTT, M.B. Fourth Edition. London: H. K. Lewis, 136, Gower Street, W.C. 1885.

SMALL 8VO VOLUME, bound in morocco leather to serve as a pocket-book, containing list of references to current literature, a review of the British Pharmacopœia of 1885—its additions, omissions, changes in nomenclature, and principal alterations, and 386 pages of text, including from page 337 onwards a Secondary List of Drugs, of some of which little or no experience has been had, and of others which are old remedies recently resuscitated. An Appendix is devoted to Antiseptic Applications and Surgical Dressings, to Histological Preparations for Staining, Hardening and Mounting Microscopic Objects, Index and Posological Table, and a Therapeutic Index of Diseases and Symptoms. The most interesting part of this little work to manufacturers of Fine Chemicals and others connected with such branch, as well as to the Research Chemist of Organic Chemistry, will be the portion devoted to the rarer alkaloids, vegetable extracts, and other organic compounds.

Obituary.

MR. CHARLES MOSELEY.

A MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

IN the sudden death of Mr. Charles Moseley, on Saturday, 8th October, Manchester has lost one of her most public-spirited, far-sighted, and energetic citizens. Besides having the practical management of the extensive indiarubber factory of which he shared the proprietorship with his brother, Mr. Joseph Moseley, he was Chairman of the Lancashire and Cheshire Telephone Company, one of the most active of the Directors of the Manchester Ship Canal, and the Chairman of the No. 7 Section of the Royal Jubilee Exhibition in Manchester, a Section having charge of the electric lighting of the building and of the gardens, of the music and of the catering. But even these duties, sufficiently heavy for any ordinary individual, only represent a fraction of all the engagements to which he so zealously, so untiringly devoted his full energies. It is well known in Manchester how much we owe to that indefatigable energy and persistent attack, which, in the contest with the Post Office—that strove under the Telegraphs Act to prevent the establishment of telephonic communication between adjoining towns—gave Mr. Charles Moseley at length the victory over that short-sighted opposition, and to his fellow-countrymen the inestimable boon of telephonic communication between towns. Thus, the present "trunk-line" system has been developed, by which it is possible for most of the Lancashire towns to hold telephonic communication with each other. When the Edison Electric Light Company was organised, his interest in electricity induced him to take a leading position, and as a Director he has always taken an active part in fostering its development and welfare.

One of the most surprising things in connection with Mr. Moseley was his quick perception. For example, it was his voice that was first raised to propose the abolition of technical juries and medal awards in connection with the Manchester Exhibition, a proposition unanimously received by the Executive Council, and adopted with the greatest benefit to the Exhibition. This fact is borne ample testimony to by the determination of the Executive of the Glasgow Exhibition of 1888 to follow in this respect the example of Manchester, and leave reward to the natural and unbiassed voice and verdict of public opinion.

Mr. Charles Moseley was born in the year 1840, and in his death he leaves a widow and three young children to mourn his loss.

Trade Report.

(From the Board of Trade and other Journals.)

GENERAL MEETING OF THE SOCIETY FOR THE PROTECTION OF THE INTERESTS OF THE GERMAN CHEMICAL INDUSTRIES.

FRANKFORT, *Sept 1th.*

The secretary of the Society submitted his business report. The result of a retrospect of the last year, 1886, is relatively favourable. In spite of a not unimportant augmentation in production, which occurred in all branches of chemical industry, the increased supply was taken up by the consumers without difficulty, so that no great accumulation of stocks has taken place. This favourable development of trade was, however, in part compensated for by a fall in the prices of many of the articles produced. In the course of the year it has been possible, chiefly through conventions, not only to put a stop to this movement, but in many instances to cause an improvement in prices. It is unfortunately not yet possible to make a statistical comparison of the activity developed during the year 1886 in the productions of the chemical industries with former years; however, in future years the statistics of the associations will furnish the suitable materials for this purpose. During the year 1886 there were in the chemical industries 23,528,498 working days, for which 61,797,490 marks were paid as wages. It is seen from the published statistics of the companies that as a matter of fact an increase in the profits occurred in almost all branches of chemical industry. In the year 1886 82 limited companies, with a paid-up capital of 162,540,842 marks, returned as dividend 11,659,895 marks, being 7·17 per cent.

This increase of profits has not taken place in all instances, but principally only in the older-established works, where large amounts have already been written off. In order to render a comparison with former years possible only those factories may be considered which have existed at least since 1881. In that case there is an average dividend of 9·25 per cent. In comparison with former years it is seen that the average dividend, which since 1882 steadily decreased, in the last year again moved in an upward direction. The average dividend of these manufactories amounted to—

For the year 1882	13·07 per cent.
,, ,, 1883	11·04 ,,
,, ,, 1884	8·42 ,,
,, ,, 1885	7·92 ,,
,, ,, 1886	9·25 ,,

If the principal branches of chemical industry be considered which paid dividends, the following results are obtained. The dividends paid in the soda and potash industries were—

In the year 1882	9·89 per cent.
,, ,, 1883	9·27 ,,
,, ,, 1884	6·54 ,,
,, ,, 1885	5·58 ,,
,, ,, 1886	5·68 ,,

It results from this, that if the turn for the better in this branch of chemical industry has not been very important, still it shows that a step has been taken in an upward direction. No branch of chemical industry within the last ten years has had such rapid development as the soda industry. While the production in the whole of Germany during 1878 only amounted to 42,500 tons, there are at present in 24 works (Getriebsstatten) 150,000 tons manufactured. This increase is almost wholly due to the introduction of the ammonia-soda process. Ten years ago the imports of soda amounted to only 27,000 tons, signifying that 40 per cent. of our requirements had to be covered from abroad. Now we are able, in spite of the immense increase in consumption, not only to supply home requirements, but we have already commenced to export. The price of the 98 per cent. calcined soda in the same time has gone down from 20 to 8 marks in spite of the increased duty.

In the Stassfurt industry (potash salts) the business in chloride of potash has been developed steadily, with unchanged prices and increased sales. The production is increased so that at the beginning of this year the daily output of carnallit has risen from 45,000 to 55,000cwt. The sales to the different countries have been fluctuating. This was particularly seen with America, which did import considerably less than in former years on account of a commercial crisis. This deficiency has been abundantly compensated for by larger home consumption, so that at the close of the year only the necessary stocks were in hand. The sales of potash salts for manure which are obtained from kainit were less favourable, as America, the chief purchasing country, took considerably smaller quantities. Still, the total sales are not much behind those of former years.

In the tar colour trade the average dividends declared by the German "Aktien Fabriken" were—

In the year 1882	20·53 per cent.
,, ,, 1883	14·06 ,,
,, ,, 1884	10·49 ,,
,, ,, 1885	6·70 ,,
,, ,, 1886	9·45 ,,

In this branch of chemical industry, likewise, reduction in prices took place, which, however, was kept within moderate limits, whilst the sales at the same time, particularly for export, rose considerably. The exports in the year 1885 were 4,645,000kilos., and in 1886 5,700,000kilos.

Respecting the manufacture of explosive materials, the following are the results. The average dividends paid were—

In the year 1882	9·39 per cent.
,, ,, 1883	10·51 ,,
,, ,, 1881	8·09 ,,
,, ,, 1885	10·01 ,,
,, ,, 1886	15·46 ,,

This favourable development of business during the last years has principally been of good to the old and large establishments, which through conventions were able to secure high export prices, and utilise suitably the fluctuations in the raw material market; while some of the more recently established factories, as the Cologne and Siegener dynamite works, have not yet, for instance, been in a position to declare any dividend to their shareholders, and lately the prospects of profits of these companies have got worse on account of the price of glycerine, which has risen from 54—60 marks, paid last year, to 106—110 marks.

The manufacturers of artificial manures (superphosphates) have again worked most unsatisfactorily. They paid as dividends—

In the year 1882	6·74 per cent.
,, ,, 1883	5·79 ,,
,, ,, 1884	4·16 ,,
,, ,, 1885	3·30 ,,
,, ,, 1886	3·52 ,,

The fault of this unfavourable result lies not so much in the small consumption as in this, that the manufacturers have been injuring themselves through constantly lowering their prices on account of the unfounded fear that the very much increasing consumption of Thomas basic slag might influence the demand for superphosphates. The efforts to form conventions remain without result. Only in some districts (Hamburg, Hanover) have the manufacturers succeeded in coming to an agreement among themselves, and here it has worked with somewhat better results, to which principally the increase in the average dividend of this year is to be ascribed.

In the production of technical, pharmaceutical, and photographic preparations the average dividends stand as follows:—

In the year 1882	11·88 per cent.
,, ,, 1883	11·05 ,,
,, ,, 1881	15·50 ,,
,, ,, 1885	15·01 ,,
,, ,, 1886	16·83 ,,

This satisfactory average is not found to occur in all branches of this industry; it is rather due to the prosperous condition of one of the most important manufactories (Schering). In this industry, also, important reduction in prices has taken place, particularly so with the alkaloids quinine, caffeine, atropine, cocaine, and veratrine. The acknowledged superiority of the German preparations, especially abroad, has also here insured an increase of sales.

Among the other important branches of chemical industry, the manufacturers of mineral colours have done satisfactory business both at home and abroad. Only the export to Austria was somewhat limited owing to the disproportionately high duty, and to Scandinavia on account of the rigorous arsenic law. Owing to strong competition, prices were only, with much difficulty, able to maintain themselves.

The condition of ultramarine has been very unsatisfactory. The cause of this is to be sought, not perhaps in over-production, but in diminished consumption, occasioned partly through the influence of fashion and partly because ultramarine is being replaced by other colouring materials. Export for inferior sorts has become impossible on account of the high duties, and can only be effected for the best varieties and for specialities. Only old and very substantial firms have been able to defy these unfavourable circumstances, and there are, as a matter of fact, in Germany scarcely two or three firms which work without loss.

The secretary reported as to the internal activity of the Society, and the work which has been carried out by the various committees.

In connection with the secretary's report, the meeting resolved to direct their efforts so that German manufactures should only be exported with German labels and German designation, and called upon the members to use their influence in their Chambers of Commerce, etc., to prevent the credit of the good products of German manufacture being given to foreign countries.

The revision of the Patent law was next the order of the day. The Imperial Enquiry Commission has rendered a report, on the basis of the enquiry discussion, to the Imperial Government, in which definite proposals are made concerning the alterations in the existing Patent Law. The Patent Law Committee of the Society has given definite counsel in these discussions concerning the position of the chemical industries; these discussions will soon be brought to a conclusion.

With respect to the original project of the Imperial Government for making provision for invalid and aged workmen, there being many alterations necessary before bringing about a discussion in the Society, the subject was adjourned.

The meeting then considered the question of insurance against fire of chemical factories. Statistics concerning the fire insurance of chemical works during the last 10 years, with a collective insurance amount of over 200 million marks, were laid before the meeting. This showed that during the stated time, on the whole 23·2 per cent. of the paid premiums have been paid back in making good losses. On the basis of these statistics, and regarding the little consideration which the insurance companies have hitherto shown to the wishes of the chemical manufacturers, the Society resolved by a large majority to instruct the committee concerning the plan of the formation of an insurance of chemical works, based on reciprocity, to take the matter into consideration, and to take in hand the necessary preliminary steps. The necessary sum for this purpose (amounting to 5000 marks) was placed at the disposal of the committee.

Respecting the reform of the Trade Marks law, a petition will be forwarded from the Society to the Imperial Chancellor, who will be requested so to frame the law, that in the intended reorganisation of the Patent Law Commission, steps be taken at the same time for the consideration of the reorganisation of the Trade Marks law. The petition included also that there might be, for the carrying out of the Trade Marks law, a distinct trade marks office established, affiliated to the patent office itself.

This official should at the same time take in hand the task of examining the already registered marks, as well as the more recent, and to publish periodically the authorised and recognised marks.

Unfortunately, for Frankfort especially, the next order of the day had to be set aside, as the work of the committees had not sufficiently advanced. It related to the pollution of public watercourses by manufacturers' waste liquors.

The work of the special committee to which has been entrusted the question of the preparatory education of chemists continues. For the present it has been decided that the real schools for the preparatory education of technical chemists shall be considered equal to that obtained in the colleges. The conclusion of academic study should not in future (as up till now) form the doctor degree, but an examination before a Government Commission, and which shall comprise certain subjects (general chemistry, chemical technology, physics, and various other allied subjects). Concerning the fixing of the proper course at the technical high schools or at the universities, the consideration shall be continued. Eventually prizes should be granted for the best papers dealing with this subject.

Two resolutions were moved by members. The first concerned the transport of mineral acids by rail; the second the needful facilities for the use of alcohol in chemical industries for general and manufacturing purposes. The meeting resolved regarding the first proposition to petition the proper quarter, and appointed a special committee (consisting of nine members) for its consideration.

MISCELLANEOUS TRADE NOTICES.

THE NEW GERMAN SPIRIT LAW.

By order of the Prussian Finance Minister alcohol for medicinal and scientific purposes has been provisionally declared exempt from the principal clauses of the new German spirit law. It is also provided that all alcohol for such purposes at present existing in Germany will remain free from the increased duty if used within three months from October 1. The authorities charged with the execution of the law have measured the quantity of alcohol in stock in Prussian pharmacies and chemical works on the 1st of this month, and nothing may be taken from the supply thus found except in the presence of the Customs officers, who will satisfy themselves that it is used for pharmaceutical or scientific purposes, a control which appears to be of a rather complicated character.—*Chemist and Druggist*, October 22, 1887.

EXHIBITION OF ILLUMINATING APPARATUS AND NAPHTHA INDUSTRY AT ST. PETERSBURG.

A report, dated the 2nd September last, has been received from Mr. J. Michell, her Majesty's Consul at St. Petersburg, enclosing copies of notices relating to an exhibition of illuminating apparatus and naphtha industry which is to be opened at St. Petersburg in November next, with the sanction of the Russian Government and under the auspices of the Imperial Russian Technical Society.

[The notices in question, containing particulars as to the exhibition, may be seen on application at the Commercial Department, Board of Trade, S.W.]

RAMIE CULTIVATION IN SAXONY.

The Italian *Bollettino di Notizie Commerciali* for the 4th September last, quoting from the *Moniteur Industriel*, states that the first German manufactory of ramie was established at Zittau. The thread produced in these looms has the brilliancy of silk, and is used largely for the upholstering of furniture. After some initial delay and disappointment, the manufacture began to flourish, and since 1883 has been in a very satisfactory state. The cultivation of the ramie is carried on in the Oberkunewalde, with the following species of plants, the *Urtica dioica* or common nettle of Germany, the *Laportia Canadensis* or North American nettle, the *Urtica nirca*, which is known as "China grass," and is a native of China, and the *Urtica tenacissima* or "ramie" proper, which was originally discovered in Siberia, then cultivated in Algeria, and afterwards introduced into central France, and lately into Hungary. The two last-mentioned species have borne the winter in Oberkunewalde with perfect success.

COMMERCIAL MUSEUM AT TREBIZOND.

According to the *Bulletin du Musée Commercial* for the 17th September last, a Commercial Museum is about to be opened at Trebizond, under the auspices of the Belgian Consulate in that city.

COMMERCIAL MUSEUM AT AVIGNON.

According to the *Moniteur Officiel du Commerce* for the 15th of September, the French Minister of Commerce and Industry has approved, by a decree of the 6th of September, the establishment of a Commercial Museum by the Chamber of Commerce of Avignon.

COMMERCIAL MUSEUM AT TOKIO.

The *Bulletin du Musée Commercial* for the 27th September last states that the Japanese Government has attached to the School of Commerce in Tokio a Commercial Museum, for the purpose of exhibiting to Japanese importers foreign articles of trade which are likely to interest them. The School of Commerce at Tokio, according to the *Bulletin*, is an important institution, containing no less than 500 students, who are being trained with a view to their spreading the latest principles of commercial science through the length and breadth of Japan. The *Bulletin* remarks that it is, therefore, of importance to European merchants to contribute to the new museum, and adds that specimens may be sent, addressed to Mr. Takashi Masuda, Hitotsubashidori, Tokio, Japan.

COMMERCIAL MUSEUM AT ANTWERP.

The *Bollettino di Notizie Commerciali* for the 4th of September states that a Commercial Museum was opened at Antwerp on the 21st of August last.

CANDLE TRADE IN CHINA.

The *Bulletin du Musée Commercial* for the 10th of September last, quoting from the *Exporteur*, states that the trade in candles with China is important, and capable of great development. The candles most in demand in China are those which are of the colour of red sealing-wax. Blue candles are used in funeral ceremonies, and there might well be made a large supply of these. At present none but white candles are imported into China, and they are surface-coloured very cheaply before being re-sold. It should be remembered in preparing candles for the China market that the Chinese prefer them with a bamboo wick projecting at the bottom, so as to be easily fixed into a hole in the candlestick.

BEET SUGAR CULTIVATION IN THE UNITED STATES.

It is stated in *Bradstreet's* of the 3rd September last that a large sugar refiner is reported to be contemplating the experiment of growing beet-root sugar in the United States, in one of the central Western States. The climate is said to be similar to that in Germany and Austria, where beet-root cultivation is a most important industry. Whether, says *Bradstreet*, under present conditions of low sugar prices it is possible to successfully make this sugar in the United States, is an interesting question. In 1886 the total consumption of sugar of all kinds in the United States was 1,389,125 tons, of which only one-tenth was produced in that country.

FILTERS WANTED FOR THE STATES.

There is a good opening in the States, says the *Medical Press*, for an enterprising manufacturer of filters. They have no filters, or if they have they do not use them. Nor is it on account of the extreme purity of their water supply, for out of many specimens examined during the past few weeks, scarcely one fulfilled the primary conditions of freedom from colours and sediment. It was to this, indeed, apart from what was mixed with the water, that the foreign delegates to the Medical Congress attributed the choleraic diarrhœa from which nearly all of them suffered during their visit.

PROBABLE ADVANCE IN THE PRICE OF PETROLEUM.

We have reason to believe, says the *Financial News*, that there is likely to be a substantial and sustained advance in the price of petroleum. We understand that, at the instance of the Standard Oil Company, steps have been taken to limit the production for a long period, and the effect of this upon values, both here and in the United States, is already beginning to be felt.

THE CHLORIDE OF POTASSIUM INDUSTRY.

According to the report of the general representative of the syndicate, the chloride of potassium business in the first half of the current year entirely fulfilled the expectations of the syndicate. The sales in the first half were generally weaker than in the second half of the current year. Nevertheless, the sales in the first half attained a higher standard than has yet been reached since the syndicate has been established, as is clear from the following figures. The sales of potassium chloride amounted :—

In the	1st	half of	1884	to	875,197	ctr.[*]

TARIFF CHANGES AND CUSTOMS REGULATIONS.

UNITED STATES.

Customs Decision.

Sugar known as "cube sugar," refined in the United States from imported raw sugars, is held upon exportation to be entitled to the rate of drawback prescribed by the existing instructions of the Treasury Department as to "refined loaf, cut-loaf, crushed, granulated, and powdered sugar," viz., $2\frac{68}{100}$ cents. per pound, less the legal retention of 1 per cent.

NEW CUSTOMS TARIFF OF BRAZIL.

(Continued from page 613 of the September Number of the Journal.)

RUSSIA.

Recent Customs Decisions.

(*Note.*—Poud = 36lb. avoirdupois. Funt = 0·902lb. avoirdupois. Gold rouble = 3s. 2d.)

Sesquicarbonate of soda.—Section 151. Duty, 10 roubles per poud gross, with an addition of 20 per cent. on each rouble of duty leviable.

Disinfecting powder, composed of carbolic acid not cleaned.—Section 16. Duty, 5 copecks per poud gross, with an addition of 20 per cent. on each rouble of duty leviable.

Mixtures of starch and borax.—Section 45. Duty, 1 rouble per poud, with an addition of 20 per cent. on each rouble of duty leviable.

Spirits of wine mixed with ammoniac and imported in bottles.—Section 77. Duty, 75 copecks per bottle

Solution of cochineal.—Section 119, Part 2. Duty, 5 roubles per poud.

Precipitate of alumina.—Section 125. Duty, 11 copecks per poud.

Pyrogallic acid.—Section 137, Part I. Duty, 4 roubles per poud.

Solution of chloric lime—Section 140. Duty, 2 roubles per poud, with an addition of 20 per cent. on each rouble of duty leviable.

Naphthalene.—Section 140. Duty, 2 roubles per poud, with an addition of 20 per cent. on each rouble of duty leviable.

It has been decided by the Customs authorities to prohibit in future the importation of *Tamar Indien*, unless it is accompanied by a statement setting forth the manufactory at which it was prepared, and an exact description of its properties.

FINLAND.

Modification of Customs Duties.

It appears from a report of Mr. Charles J. Cooke, British Vice-Consul at Helsingfors, dated the 5th September last, that the Imperial Finnish Senate has decreed that raw asbestos and asbestos powder should be imported into Finland duty free, while all goods made of asbestos should pay a duty on importation of 12 marks per 100kilos., with an addition of 20 per cent. if these goods consist of ready-made clothing of asbestos.

CONSULAR REPORTS.

CHILI.

Saltpetre Exports.

19,230,047 pesos, or two fifths of the whole exports of Chili, are represented by saltpetre. Signs are not wanting that the production of saltpetre is to be materially reduced, and the effects of this upon consuming markets in Europe will be considerable. It is estimated that of the total quantity exported, one-third finds its way to England, the remaining two-thirds going to the Continent. The average freight is £1 10s. per ton, the vessels employed being mostly sailing ships. The Italian Florio-Rubattino Co. is beginning to ship direct to Italy.

EGYPT.

Candles, etc.

The French Consul at Alexandria, in his report, says that France supplies wax candles very largely. Nearly all those consumed come from the Marseilles factory of M. Fournier. The activity and enterprise of this firm have succeeded in establishing almost a monopoly of the trade. For several years Austria endeavoured to find a market in Egypt for these goods, but all serious competition has now been abandoned. As to the English products they exist only in the Customs returns. They are either manufactures which have been warehoused in England or transported to Egypt by English steamers. The strongest competition which French manufacturers have to face comes from Belgium. It is calculated that Belgian traders, owing to the smaller charges on their industry, can save five francs per 100kilos. in the manufacture of their goods, compared with the cost of producing French products. This makes Belgian competition serious. French manufactures, however, still maintain superiority in quality to those of other countries.

According to the Belgian Consular Agent at Mansoorah, Belgium has for some years competed strongly with French products. Belgian prices are lower than those of the French, and if the natives had not had a superior article offered to them at less cost, they would not have purchased as they have done from Belgian traders. French wax candles are still very much sought after at the present time, but now there are competitors in the field the prices have been very considerably reduced.

HOLLAND.

Candles.

The imports of wax lights and candles, says the Secretary of the Belgium Legation, at the Hague, are unimportant, and tend to be still further reduced. In 1881 they amounted to 21 000 florins, while in 1885 they were only valued at 14,000 florins. Candle factories at the Hague are important, although not numerous; the "Apollo" factory, established in 1869, and employing between 400 and 500 men, being the chief one. The candles turned out by this factory are not only employed throughout Holland, but are used in all parts of the world. Each year the factory consumes between 8000 and 9000 tons of tallow from Austria, America, or Russia. The factory is a prosperous concern. It manufactures candles of all kinds, shapes, sizes, and colours. The total export of candles in 1885 was 7,244,000kilos., a decline of upwards of 2,000,000 kilos. on 1881.

The Chemical Industry.

The chemical industry is not as flourishing as it used to be. Dutch manufacturers of chemical products are now seeing Germany, their best market, closed to them owing to the high Customs duties of that country. Germany, however, still remains the best market for Dutch chemical products. Dutch manufacturers have since sought to establish a new trade with this country.

Soap Manufacture.

Soap making during the past few years has, from a manufacturing point of view, made considerable progress. Dutch soaps are partly consumed in the country and partly exported to the Dutch East India possessions, where they bid fair to successfully compete with the English and French products, which until recently were the only kinds known. The soap works are divided into two principal categories, those which manufacture soft soap, which are the most numerous, and those that make the hard soap. In 1883 there were sixty-six manufactories of the first kind and thirty-three of the second, which produced 17,831,000kilos. The toilet soaps the most estimated are those bearing the mark of Sanders & Co., of Leyden. This firm is equally noted for the best makes of soap as for the commoner kinds. This industry has not been so flourishing lately, as protective duties have been adopted in the countries which offered the best openings. It has suffered also from English, French, and German competition, the raw materials in these countries being cheaper than in Holland. Belgium, Africa, and the Dutch possessions are the chief markets for Dutch soaps.—*Brit. and Col. Druggist.*

OUR TRADE LAST YEAR.

The year 1886 was a year of marked commercial depression, and we therefore cannot expect to find very satisfactory reading in the annual statement of the trade of the United Kingdom with foreign countries and British possessions which has just been issued in the form of a bulky Blue Book. We imported during the year merchandise to the value of £349,863,472, a less value than in any year since 1882 inclusive. To this amount, foreign countries contributed £267,979,429, and British possessions £81,884,043, in each case a diminution upon the figures for any corresponding period during the previous four years. Our exports during the year amounted to £268,667,017, again a less figure than in 1885, 1884, 1883 or 1882. British produce contributed to this sum £212,432,754, and foreign and colonial produce £56,234,263, in each case the smallest amount in the five years. It is significant that the falling off in our exports last year, in comparison with 1885, was due to a decreased demand in our own possessions. While we sent to foreign countries goods to the value of £186,599,306, an improvement of nearly a million upon the preceding year, our exports to British possessions only amounted to £82,087,711, as against £85,424,218 in 1885.

Turning to the articles in which our readers are mainly interested, we find that the drugs unenumerated, Peruvian bark, and opium, imported last year were valued respectively at £669,979, £801,353 and £307,666, in each instance a considerable falling off in comparison with the figures for any of the preceding four years. Our imports of alkali amounted to £55,828, again a smaller sum than in any other of the five years, while our imports of chemical manufactures and products are put down at £1,281,537, which figures also compare unfavourably with those for the former years.

On the export side, which is of course the most important, we find a falling off under almost every item. The value of our exports of medicines, drugs and medicinal preparations is put down at £814,213 as against £842,725 in 1885, £893,184 in 1884, £922,649 in 1883, and £935,233 in 1882. We exported alkali to the value of £1,788,078 as against £1,955,790 in 1885, and still larger sums in each of the three preceding years. One of the few redeeming features in the character of our exports during the past year is to be found under the head of chemical products and preparations, our exports of which were valued at £1,492,574, an improvement upon each year of the five with the one exception of 1882.

The statement before us also contains a table showing the total value of the articles of foreign and colonial produce and manufactures exported. From this table it appears that the values of the drugs unenumerated, Peruvian bark and opium, of this class exported, were respectively £363,398, £517,794 and £215,868. All these figures compare badly with the figures for the preceding four years, with the exception of those relating to opium in 1882.

One of the most interesting parts of the compilation from which we take the figures given above is that portion which shows the extent of our imports and exports from and to the different foreign countries and British possessions. From this it appears that of the drugs unenumerated brought into the country, foreign countries contributed to the value of £508,880, and British possessions to the value of £161,099. The United States, the British East Indies, Holland, and France sent us the largest amount. What is tabulated as Peruvian bark—though why does not appear was imported from foreign countries to the value of £167,688, and from British possessions to that of £633,669. For Peruvian (?) bark we were indebted chiefly to Ceylon, Madras, the United States of Columbia, and France. The value of opium imported from foreign countries and British possessions is put down respectively at £298,682 and £8981. Turkey sent us this drug to the value of £239,662 and Persia to that of £50,727. £31,885 and £23,913 represent the value of the alkali imported last year from foreign countries and our possessions respectively. Our imports from British North America amounted to £23,930, from Holland to £11,313, and from France to £10,532. Our imports of chemical manufactures and products from foreign countries amounted to £1,269,527, while those from British possessions are put down at £15,010. France, Holland, Germany, and Italy were our largest suppliers.

Turning again to the export side, we find that last year we exported alkali to foreign countries to the value of £1,666,454, and to British possessions to that of £121,624. America was by far our largest customer for this article, Russia and Spain coming next, a long way behind. Our exports to foreign countries of chemical products or preparations not specially enumerated amounted to £1,219,532, while those to British possessions were estimated at £273,042. The United States, France, and Germany took the largest quantity. Of medicines, comprising drugs and medicinal preparations, we exported to foreign countries to the value of £306,323, and to our own possessions to that of £507,890. Australasia and India were our largest customers.—*Brit. and Col. Druggist.*

The Rock Salt of Belfast and Carrickfergus.

Mr. Robert Hanoa, of Belfast, has published a letter with regard to local industries. In that communication he says:—

"It is now almost half a century ago since Sir Robert Kane wrote that the strata in the vicinity of Belfast corresponded with that of Runcorn, near Liverpool; for all that, he remarked, there was no rock salt in the vicinity of Belfast.

"If this scientist did not hit the mark, he took a good aim at all events, for in the hills at Carrickfergus for many a year there appeared a well of water that was continually sending up bubbles. People wondered at this phenomenon. At last the boring-rods went down, and rock salt was found to explain the phenomenon.

"And now we come to a greater wonder. Here, within a few miles of Belfast, there are several rock salt mines. One of them, 'Logan's,' contains 100ft. of a solid seam. The manufacture, like the others in full operation, has a siding to the railway within a few miles of Belfast, and for all that there was imported last year from England nearly 6000 tons of manufactured salt. At Runcorn the mines are flooded to produce brine. At Carrickfergus the rock salt is lifted from the mine, melted, and conveyed by pipes to the pans. This prevents the salt water from being in any way impregnated with terrene matter. And as for the samples of rock and manufactured salt of Carrickfergus, I, as a geologist, proclaim them to be the finest samples in God's five broad continents. For all that, how does it come this vast importation of manufactured salt into Belfast? It is surely shipping coals to Newcastle with a vengeance. It is wonderful the mania we have at present for the importation of everything we use from England. Even the Tramway Company and the Town Council must have every stone for square sets from England. *Mais revenons a nos moutons.* Lately there has been a prospectus issued and sent to this country from, I believe, the vicinity of Runcorn, near Liverpool, enlarging on the merits of a company that is about to be formed for the manufacture of soda ash, crystals, bleaching powder, etc. Of course, the materials are at hand for the manufacture of these commodities, and it would appear 'a patent' is in the background to forward this important scheme. Wishing this company every success, I would like that these 'patents' that are issued should be confined to the respective countries of England, Ireland, and Scotland. It creates a monopoly that is highly injurious to the countries not interested. For instance, it is well understood we have salt in millions of tons at Carrickfergus; we have limestone and coal slack cheap enough; ammonia in abundance in Belfast. For all that, it may happen that for fully fifty years we will be debarred the manufacture of these chemical ashes, although all the materials are at hand. Consequently we lose thousands on thousands of pounds to the capitalist and loss of employment to our local population. Formerly in Ballymacarrett this industry of the manufacture of chemical ashes was carried on on a very extensive scale, but English monopoly ruined it. Now, it is understood the Ballymacarrett manufacturers were not able to hold their ground, when at Runcorn they had all the materials at hand—viz., lime, salt, ammonia, etc.; but things do change, and here at Carrickfergus we have lime and salt in inexhaustible supplies, ammonia cheap enough, and coal slack at a nominal rate could be landed near Eden at a very cheap item.

"Now, last year there were imported into Belfast soda ash and soda crystals, 3983 tons; bleaching powder, 2177 tons; and soda ash, 3128 tons. This is not taking in the quantity imported into Larne. Now, in handing out patents, I do maintain that these patents should be confined to the several countries interested, for why should a patent of any individual debar another country from developing its great resources? It looks also very strange to see almost 6000 tons of manufactured salt imported into Belfast last year, and millions of tons of it at our own doors; and, if an effort was only made, we should be able to ship it to all parts of the world, instead of only shipping one single ton last year.

"Now, there are three salt mines open at present in Carrickfergus, and—would it be believed!—the rock salt has been found in the vicinity of Belfast, and the owner is afraid to let it be known for fear of too high a rate of royalties! And, if we are not capable of manufacturing chemical ashes, perhaps we might be allowed to open our salt mines, manufacture and sell it."

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

APPLICATIONS.

12804 J. Parsons, Liverpool. Method and apparatus for preventing incrustation in steam boilers

12876 F. Livet, London. Steam generator, its flues and furnaces, with feed water combination, for producing heat and steam. September 22

12963 A. Siegert and W. Dürr, London. Devices for measuring the density of gases. September 24

12986 J. Vicars, T. Vicars and J. Vicars, jun., Liverpool. Furnaces of externally-fired steam generators. September 26

13015 W. R. Lake—From Madme. Marcoux, France. Apparatus for raising liquids. September 26

13017 P. A. Newton—From Theisen and Langen, Germany. Apparatus for cooling or heating liquids and air. September 26

13043 H. Wilson and A. Wilson, Stockton-on-Tees. Apparatus for injecting air, gas, oil or other fluids into furnaces, for increasing draught, reducing smoke, and assisting combustion. September 27

13105 J. Butterworth, Rochdale. An improved valve. September 28

13256 F. W. Allchin, London. Apparatus for mixing substances or materials in a dry state. September 30.

13266 A. T. Clarkson, London. Valves for regulating the flow of gases under pressure. September 30

13395 H. Kilburn, Bishop Auckland. Valves for regulating the flow of fluids. October 4

13431 W. P. Thompson—From W. B. Wright and E. T. Williams, United States. Improvements in furnaces burning hydrocarbons. Complete specification. October 4

13483 W. E. Carrington and J. Brocklehurst, London. Kilns for calcining limestone, iron ore, and for other analogous purposes. October 5

13667. L. Perkins, London. Cooling and refrigerating apparatus. October 8

13852 J. Spencer, Glasgow. Reverberatory furnaces for heating, metallurgical, glass making and similar operations. October 13

*COMPLETE SPECIFICATIONS ACCEPTED.**

1886.

14682 L. Rouviere. Generation, application and utilisation of steam, and apparatus therefor. September 28

15076 C. A. Sahlstrom. Apparatus for projecting oil or other fuel into furnaces in the form of spray. September 28

15125 F. L. Merritt. See Class II.

15158 J. E. Hodgkin and E. Perrett. Filters. September 21

15171 T. Richmond—From W. Wills. Apparatus for the separation of smoke from the gases evolved during combustion of fuel. September 21

15176 E. M. B. Faull and F. W. Cannon. Method and apparatus for prevention of corrosion in steam boilers. September 28

15240 O. Bowen and J. Cobeldick. Deodorising, decolorising and filtering medium. September 28

16029 C. de Montgrand. Process and apparatus for the production of heat and cold. October 12

16525 F. C. Bond. Apparatus for heating liquids by steam. October 19

16547 J. Atkinson. Refrigerating apparatus. October 19

---

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

1887.

3719 M. Kotyra. Electrical apparatus for prevention of corrosion and scale in steam boilers. September 28

3804 J. Howes. Filtering apparatus. October 19

5251 G. E. Wright. Valve for regulating passage of gas. October 5

9077 S. Pitt—From J. R. Knapp. Blowpipe apparatus for producing intense heat and artificial light. October 12

9206 J. Howes. Rotary filtering apparatus. October 19

11139 R. Johnson. Air compressors. September 24

11284 J Smeaton and J. D. Simpson. Valves for controlling the flow of liquids, gases and steam. October 19

12210 J. T. King—From H. Kennedy. Hot blast stoves and furnaces. October 12

II.—FUEL, GAS AND LIGHT.

APPLICATIONS.

12801 A McKune Margerison, London. Improvements in fire lighters. Complete specification. September 21

12946 W. Guest and others. See Class III

13096 R. Wallwork and A. C. Wells, London. Self-generating oil, gas, or vapour burners, and arrangements connected therewith. September 28

13388 J. Atkinson, London. Improvements in gas-making apparatus. October 4

13450 S. R. Dickson, London. A process and apparatus for the manufacture of gas for heating and illuminating and of cyanogen or some of its compounds. Complete specification. October 4

13521 W. Gadd and W. F. Mason. Manchester. Improvements relating to the construction of gas-holders. October 6

13544 P. Jensen, London—From J. Leete and V. D. Stockbridge, United States. Improvements in Carburettors. Complete specification. October 6

13627 E. Kenyon, Manchester. Improvements in the production of illuminating gas, ammonia and other products, and in apparatus therefor. Complete specification. October 8

13734 K. R. Kilbourn, London. Improvements in methods of generating heat. October 11

13922 J. Y. Johnson—From C. Bertou, France. A new or improved compound for lighting and heating. October 13

13993 W. Wilkie, Glasgow. An improvement in effecting the combustion of fuel. October 15

14085 H. J. Fenner and G. H. Fenner, London. Improvements in the manufacture of naphthalene into forms suitable for use in illumination and in apparatus employed therein. October 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8348 J. Hammond. Method and apparatus for purification of coal gas by concentrated liquid ammonia, and the recovery of sulphur and ammonia for the manufacture of sulphuric acid and sulphate of ammonia. October 1

12610 H. Suteliffe. Utilising the waste heat of gas and combustion explosive motor-engines for heating water. September 24

14395 J. Hammond. Method of and apparatus for the utilisation of gas tar. October 12

15125 F. L. Merritt. A retort fire bar to generate water gas as fuel in furnaces, where the ordinary fire bar is used. October 5

15287 J. S. Sellon. Apparatus to be employed in lighting and heating. September 24

15716 S. Cutler. Apparatus for the distribution of liquid in gas scrubbers. September 28

15728 F. J. Jones. Method and apparatus for manufacturing gas for illuminating, etc. October 5

16581 A. Paget. Use and construction of mantles for incandescent gas-lighting. October 15

1887.

11439 W. C. P. Asselbergs. Hydraulic mains for gas works. September 24

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

12946 W. Guest, T. Guest, G. Guest, and A. Guest, Mapplewell. An invention to take the waste gases from coke ovens to fire boilers and light works, and to make shale and waste dirt into oxide of iron and calcine and creosote oil. September 24

13366 W. L. Wise—From The Actien Gesellschaft fur Chemische Industrie, Germany. New process of manufacturing retene from resin oil. October 3

13462 T. Nicholson, Beeston. Improvements in the construction of coke ovens designed to secure the by-products. October 5

COMPLETE SPECIFICATION ACCEPTED.

1886.

15772 R. B. Tennent. Destructive distillation of shale and other minerals, and retorts therefor. October 1

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

12736 R. Ashton. Manchester. An improved method of preparing blue for laundry use. September 20

13088 B. Willcox—From The Farbenfabriken vormals. F. Bayer & Co., Germany. Improvements in the manufacture of methylen chloride. September 27

13950 S. E. Ganyon—From P. Fournayre, France. New or improved colouring matters and methods or processes for the preparation thereof. October 8

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

126 H. J. Walder. Production of colouring matters from carbolic acid and other phenols. October 15

127 H. J. Walder. Producing colouring matter from anthraquinone. October 15

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

13593 C. B. Warner. London. A process for rendering fabrics and other articles water repellent. Complete specification. October 7

13669 I. Singer and M. W. Judell. London. An improved process for obtaining cleansing and other products, applicable also to the extraction of oils, and similar purposes, together with an apparatus for carrying the same into effect. Complete specification. October 10

13743 P. M. Matthew, jun., Edinburgh. Improvements in the manufacture of indiarubber waterproof textile fabrics. October 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15343 W. Mather. Apparatus for treating textiles with liquids, gases, or vapours. September 24

15599 J. B. Whiteley and W. Whiteley. Machinery for drying wool and other fibre. October 1

15600 J. B. Whiteley and W. Whiteley. Machinery for washing and scouring wool and other fibrous substances. October 1

1887.

11570 S. S. Bromhead—From U. C. Allen. Apparatus for separating wool, silk, etc., from vegetable fibre or matter. September 28

11665 W. Nelson and E. Bowen. Machine for drying wool. September 28

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

APPLICATIONS.

13145 W. J. S. Grawitz, London. Improvements in dyeing vegetable and animal textile materials before spinning. Filed October 4. Ante-dated March 4 under International Convention.

13896 A. J. Boult—From W. S. Alexander, United States. Improvements in the dyeing of wool tops and in apparatus therefor. Complete specification. October 13

13944 J. S. Knott, London. Bleaching and finishing all descriptions of textile fabrics, yarns and all fibrous substances. October 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

14971 E. Sutcliffe and G. E. Sutcliffe. Apparatus for bleaching, damping, and dyeing loose fibre yarns, threads, etc. September 28

15258 T. Lebrowski. Method and apparatus for washing, scouring and bleaching wool. September 24

15135 R. Holt. Method and apparatus for dyeing warps Turkey red, alizarin red and other fancy colours. September 28

1887.

7710 E. Boursier. Dyeing fabrics and apparatus therefor. October 8

11426 E. W. Wrigley. Method and apparatus for passing warps into and receiving them from dyeing machines and drying cylinders. October 12

11497 A. Graemiger. Processes and apparatus for dyeing, scouring, bleaching and otherwise treating yarn in cops. September 24

12358 T. Sampson and F. H. Jealous. Dyeing yarn and other fibrous materials and apparatus therefor. October 15

VII.—ALKALIS, ACIDS AND SALTS.

APPLICATIONS.

13001 W. P. Thompson From S. Wolf, Germany. Improvements in or connected with the application or utilisation of acid sulphate of soda in the manufacture of cellulose and for other purposes. September 26

13018 J. Beveridge, Frodsham. Improvements in the manufacture of sulphuric acid. September 27

13061 P. Bateson and M. C. Arnholtz, Liverpool. Improvements in or connected with the manufacture of carbonate of soda from the bicarbonate of soda made by the ammonia soda process. September 27

13323 E. Solvay, London. A new or improved revolving furnace for the decomposition of bicarbonate of soda. October 1

13336 J. E. Johnson—Johnson, London. Improvements in the manufacture of acetic acid and in apparatus therefor. October 1

13617 C. Heinzerling, Berlin. A process for separating chlorine from gas mixtures. October 8

13618 C. Heinzerling. Improvements in a furnace for decomposing chlorides of metals. October 8

13695 C. Huggenberg, London. Processes for obtaining nitrates, chromates, manganates, permanganates and arsenates. October 10

13746 B. J. B. Mills From T. B. Fogarty, United States. A process of and apparatus for manufacturing ammonia. Complete specification. October 11

13747 B. J. B. Mills—From T. B. Fogarty. A process of and apparatus for producing sulphate of ammonia. Complete specification. October 11

13983 D. Herman, Liverpool. Improvements in the manufacture of sulphate of soda and in apparatus therefor. October 15

14000 F. Bale, Droitwich. Improvements in the manufacture of ammonia and hydrochloric acid and in the apparatus employed therein. October 15

14001 F. Bale, Droitwich. Improvements in the manufacture of ammonia and chlorine and in the apparatus employed therein. October 15

14016 G. E. Davis, Manchester. An apparatus for extracting arsenic from oil of vitriol and muriatic acid, and for the absorption of gases by liquids and by substances held in suspension in liquids. October 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

8348 J. Hammond. See Class II.

14875 J. R. Francis and F. F. Jones. Process and apparatus for obtaining sulphur, etc., from ores, and for purifying such substances. October 1

15391 S. H. Croll. Distillation of ammoniacal and other liquors, concentration of liquids and salts in solutions and apparatus therefor. October 5

15188 W. Burns. Manufacture of sulphate of soda and bleach in one operation under high pressure, and apparatus therefor. October 15

15198 W. Bramley and W. P. Cochrane. Treating solutions of calcium chloride so as to obtain magnesium chloride and other products. October 15

16118 H. Kenyon. Production of sulphide of zinc and chloride of ammonium. October 12

1887.

62 W. Donald. Production of chlorine from hydrochloric acid gas. October 19

11492 H. H. Lake—From A. Kayser, H. Williams, and A. B. Young. Production of caustic alkali, carbonates of the alkaline metals, muriatic acid, etc. September 21

11493 H. H. Lake—From the same. Producing silicate of sodium or of potassium. September 24

11491 H. H. Lake—From the same. Producing muriatic acid. September 21

11500 C. J. E. de Haën. Manufacture and application of the compounds of fluoride of antimony with the chlorides or sulphates of sodium, potassium or ammonium. October 1

VIII.—GLASS, POTTERY AND EARTHENWARE.

APPLICATIONS.

12765 M. W. Samuel, London. Manufacture of a plastic compound, and treatment thereof, for the production of moulded and decorated tiles, slabs and other articles. Sept. 20

12835 T. A. Green, S. Green, and H. Leak, London. Improvements in the manufacture of box cranks or rings for use in baking china or the like, and in apparatus therefor. September 21

13022 J. F. Carey, London. Improvements in the formation of tiles for roofing and such like purposes. September 26

13211 J. H. Greathead. See Class IX.

13502 T. B. Gibson, London. Improvements in the manufacture and ornamentation of vessels to imitate earthenware, china, porcelain, terra-cotta and such like. October 5

13577 J. Emery and H. Lockett, Longport. Improvements in the method of decorating potteryware. October 7

13591 E. Leak, London. An improved method of supporting plates, saucers, dishes and other similar potteryware while being fired. October 7

13723 C. Amand-Durand and R. P. Engelmann, London. Improvements in decorating glass, and in apparatus therefor. Complete specification. October 10

13852 J. Spencer. See Class I.

14028 G. F. Chance, London. New or improved machinery for rolling glass. October 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12990 J. Armstrong. Manufacture of glass, opal crystal porcelain, etc., and apparatus therefor. October 8

14519 A. Oestreicher. Machines for cutting, grinding, and polishing glass. September 24

16268 J. Armstrong. Blowing and moulding glass, and apparatus therefor. October 12

16366 A. D. Brogan and A. M. Malloch. Manufacture of rippled glass and apparatus therefor. October 15

1887.

10812 J. Earle, G. Bourne, and T. Bourne. Apparatus for cutting and ornamenting glass. September 21

11496 A. J. Boult—From F. Czech. Decorating ceramic ware. October 15

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

12775 W. R. Manders, London. Red or white-faced stock bricks. September 20

13180 J. Hargreaves, Liverpool. Improvements in the manufacture of cement. September 29

13211 J. H. Greathead, London. A method of moulding articles in cement or other semi-fluid setting material. September 29

13322 E. Solvay, London. Improvements in lime kilns. October 1

13167 W. Smith, Dublin. Improvements in the manufacture of cement. October 5

13531 T. C. Hutchinson, Stockton-on-Tees. Improvements relating to the treatment of blast furnace slag for the manufacture therefrom of hydraulic or similar cement. Oct. 6

13902 R. Punshon, London. Paving, flooring and roofing material. October 13

X.—METALLURGY, MINING, ETC.

APPLICATIONS.

12741 G. G. Mullins, London. A process of purifying, hardening and otherwise greatly improving iron. Complete specification. September 20

12747 A. J. Boult—From E. E. Ries, United States. Improved method of and apparatus for welding and tempering metals. Complete specification. September 20

12751 W. P. Thompson—From A. J. A. Lagane, France. Improvements in rollering machines or apparatus for imparting a given form to iron plates, called in France "machine a Galbord." September 20

12761 S. Massey, Manchester. Improvements in presses for forging, cutting, punching, beading and otherwise operating on iron, steel, or other metals or alloys or other materials. September 20

12856 C. A. Burghardt and W. J. Twining, Manchester. Improvements in the production of aluminium and aluminium bronze. September 22

12861 S. Dawes and W. Smith, London. An improved process for converting iron into steel. September 22

12883 C. Philippart, London. Improved method of and apparatus for producing finely-divided metal, especially for use in secondary batteries. September 22

12887 W. P. Thompson—From A. Schneider and Co., France. Improvements in or appertaining to the hardening or tempering of steel or steely iron. September 23

12912 R. R. Gubbins, London. Improvements in rolls for rolling metal. September 23

12951 J. Dennis, Sheffield. Improvements in miners' safety lamps. September 24

13150 G. F. Redfern, London—From J. Molas, France. An automatic apparatus for indicating the presence of explosive gases. September 28

13177 T. Appleby, Middlesbro'-on-Tees. An improved construction of ingot moulds and a better method of casting various shaped iron or steel ingots. September 29

13212 G. Hatton, London. Improvements in the open-hearth method or process of manufacturing iron and steel, and in furnaces employed therein. September 30

13321 J. Nicholas and H. H. Fanshawe, London. A new and improved method for the recovery of the precious metals and platinum. October 1

13325 J. Nicholas and H. H. Fanshawe. An electro-chemical process for the recovery of the precious metals. October 1

13318 J. Cooke, Birmingham. Improvements in safety lamps. October 3

13157 J. H. Smith and J. Talbot, Birmingham. Improvements in the manufacture of bars from scrap iron, applicable to other like purposes. October 5

13183 W. E. Carrington and J. Brocklehurst, London. See Class I.

13522 C. A. Burghardt and W. J. Twining, Manchester. Improvements in the production of aluminium. October 6

13560 J. Butler, London. Improvements in machinery for compressing iron or metal scraps for the manufacture of bars therefrom. October 6

13570 T. R. Weston, London. An improvement in the manufacture of steel forgings and the like. October 7

13586 H. de Mosenthal, London. Improvements in cartridges for blasting and shot firing in mines October 7

13787 W. Blackwood and T. Blackwood, jun., Edinburgh. An improved machine for corrugating metallic plates or tubes, or for corrugating and bending metallic plates. Oct. 12

13852 J. Spencer. See Class I.

13926 W. H. Penning and H. G. Owen, London. Improvements in apparatus for saving fine or flour gold in milling, hydraulising and sluicing. October 14

13938 M. Adams and J. Jenkins, London. Improvements in ventilating mines and in means employed in connection therewith. October 14

13950 M. Darnbrough and E Darnbrough Drighlington. The saving of waste of material in the tempering and coating of steel or iron wire by molten lead, of mixture of lead and tin, or tin, or during the galvanising of wire with zinc. October 14

14001 S. Dawes and W. Smith, London. An improved process for converting iron into steel. October 15

14015 C. Auty, London. An improved method of, and apparatus for, electrically lighting miners' safety lamps whilst locked, and which is also applicable to lighting other lamps. October 15

14051 D. G. Fitzgerald, London. An improved electrochemical process for the extraction of the precious metals from their ores. October 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12128 E. R. Cummios—From G. P. Schweder. Extracting gold and antimony regulus from auriferous antimony ore. September 28

13073 A. Parkes. Extracting gold, silver, and other metals, from ores or compounds containing the same. October 12

14020 J. T. Dann—From A. Schaag and Messrs. Flurscheim & Bergmann. Galvanising iron and steel October 19

14875 J. R. Francis and F. F. Jones. See Class VII.

15308 C. W. Crossley. Apparatus for the separation, extraction, and amalgamation of metals. September 28

15531 A. E. Tucker and F. W. Harbord. Materials used in the construction of metallurgical furnaces and converters. October 1

15535 R. Dixon. Apparatus for purifying coal or like material by the washing process. October 1

15790 W. G. Copestake and C. Jones. Converting or reconverting old steel, iron and other kinds of metal into compounds known as the different kinds of steel. October 15

15916 J. Clark. Obtaining alloys of aluminium with certain other metals. October 8

15993 A. W. Conquist and C. O. Lundholm. Fuse for mining purposes. October 15

16923 E. Vlasto. Apparatus for cleaning and pickling metals and utilising the used liquids. October 19

1887.

624 H. H. Lake—From J. Illingworth. Manufacture of metal ingots, and apparatus therefor. October 15

10614 L. Mellett. Apparatus for indicating the presence of mineral ores or metallic substances. October 8

10922 C. Roth. Safety apparatus for igniting fuses in blasting operations, and for preventing explosion of fire damp. October 1

11174 P. C. Gilchrist. Manufacture of steel and ingot iron by the basic process. September 24

XI.—FATS, OILS AND SOAP MANUFACTURE.

APPLICATIONS.

13017 J. W. Paton, Liverpool. A new or improved cleansing powder or compound. September 27

13085 W. P. Thompson—From La Société Industrielle des Glycerine et Acides gars, France. Improvements in the treatment and distillation of fatty acids, and in apparatus therefor. September 27

13139 M. J. Whibley, H. G. Whibley, and A. Williams, London. Improvements in soap making. September 28

13499 W. E. Heath, London. Improvements in the manufacture of scented and coloured soaps, and apparatus for making the same. October 5

13669 I. Singer and M. W. Judell. See Class V.

13739 J. McClure, C. Paton, and J. Wilkinson, Manchester. Improvement in the plates of presses for the extraction of oil from seeds. October 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

13865 H. G. Nixon and W. Stewart. The preparation of iodised oil. October 1.

16086 J. Butler and J. Evans. Apparatus for carrying or lifting patterns, or removing patterns from the sand, etc. October 1

XII.—PAINTS, PIGMENTS, VARNISHES AND RESINS.

APPLICATIONS.

13286 S. Washington, Manchester. An improved compound for application to leather as a stain or varnish. October 1

13400 S. C. Rowell and J. W. Newell, London. Improvements in the manufacture of plumbic oxide or litharge, and in apparatus employed therein. Complete specification. October 4

13885 A. G. Wass, London. A new or improved combination of substances for the manufacture of varnish, paint, enamel, and other similar articles. October 13

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

9122 J. F. F. F. Lowe. Process of manufacturing white lead. September 28

12031 H. J. Allison—From G. W. Banker. Paints and paint compounds. October 8

XIII.—TANNING, LEATHER, GLUE AND SIZE.

APPLICATION.

13012 C. J. Viscount d'Hauterive—From A. Bedu, France. Improvements in tanning. September 26

XIV.—AGRICULTURE, MANURES, ETC.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

16214 T. B. Wilson. See Class XVII.—B.

17000 A. W. Carlson. Process and apparatus for utilising urine as manure. October 12

XV.—SUGARS, GUMS, STARCHES, ETC.

APPLICATIONS.

12834 N. Tscherikowski, London. An improved process of producing refined sugar from raw sugar. September 21

13643 W. Hoskin, Halifax. A new or improved treatment of lump sugar. October 8

13671 H. Siebert, London. A process for and materials used in the production of a substitute for gutta-percha. October 8

13955 S. Fisk, London. Improvements in apparatus or devices for the treatment of sugar cane. Complete specification. October 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15240 O. Bowen and J. Cobeldick. See Class I.

1887.

7119 C. Steffen. Process for systematically lixiviating raw sugar by means of aqueous alcoholic or other saccharine solutions. October 19

12596 C. H. J. Franzen. Manufacturing white lump or loaf sugar directly from boiled refinery mass. October 19

12597 C. H. J. Franzen. Process and apparatus for treating raw, clarified or perfectly white sugar masses in loaf forms by means of the centrifugal machine. October 19

XVI.—BREWING, WINES AND SPIRITS.

APPLICATIONS.

12988 J. Bonthrone and R. B. Bonthrone. Falklands. Improvements in brewing. September 26

13031 A. de Gaulne, London. Improvements in apparatus for filtering alcoholic beverages. September 26

13102 C. C. Clausen, London. Improvements in furnaces for malt kilns. Complete specification. October 4

13840 A. H. Huntley, Newcastle-on-Tyne. An improved process for the manufacture of yeast and vinegar. October 12

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15175 J. C. Mewburn—From L. Teilliard. See Class XX.

15896 W. P. Thompson—From S. Bensaude. Manufacture of alcohol from manioc. October 8

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, ETC.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

13049 J. Allegretti, London. Certain improvements in a preserving system for perishable articles. Complete specification. September 27

13315 T. Carroll, Dublin. Preserving milk, cream, butter, meat, fish, eggs and other foods. October 3

13829 W. R. Baker, A. L. Savory and C. Ekin, London. An improved preparation of milk. October 12

B.—SANITARY CHEMISTRY.

13271 T. Donnithorne, London. Improvements in the treatment of sewage. September 30

13539 J. Bates, Liverpool. Improvements in and relating to the purification of sewer gas and noxious vapour. October 6

13781 W. Mann, London. Improvements in refuse burners. Complete specification. October 11

13943 J. H. Porter, G. Porter and J. Porter, London. Improvements in filtration in relation to the process known as Clarke's process, and to other purposes. October 14

13996 G. Roger, London. Improvements in water purifiers and sludge separators. October 15

COMPLETE SPECIFICATIONS ACCEPTED.

A.—CHEMISTRY OF FOODS.

1886.

16270 C. D. Abel—From C. Linde. Process and apparatus for making clear ice. October 5

16950 R. Glover. Dog biscuits. October 15

1887.

12035 H. H. Lake—J. H. Stebbins, jun. An improved food compound. October 8

B.—SANITARY CHEMISTRY.

1886.

13007 J. C. Butterfield and H. H. Mason. Treatment of sewage, and recovery of valuable products therefrom. October 8

15240 O. Bowen and J. Cobeldick. See Class I.

16244 T. B. Wilson. Treatment and purification of sewage and other liquids, and obtaining fertilisers therefrom. October 15

16161 F. D. Brown—From A. Howatson. Treating sewage, and apparatus therefor. October 12

C.—DISINFECTANTS.

1886.

14685 H. E. Harris. Manufacture and application of antiseptic, disinfecting, curative and healing agents. October 12

1887.

2831 J. H. Harford and W. W. Reeves. Disinfecting and curative device, and composition to be used therewith. October 5

4283 Dr. A. Dupré and C. N. Hake. Preparation of disinfectants, deodorants and antiseptics. October 15

XVIII.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

12883 C. Phillipart, London See Class X.

12885 G. E. Cabanellas, London. Improvements in dynamo-electric or magneto-electric machines. September 22

13080 W. Fritsche, London. Improvements in and relating to dynamo-electric machines. September 27

13159 W. W. Dunn, London. Improvements in electromotors and dynamo electric machines. September 28

13309 C. V. Burton, London. A new dynamo-electric machine. October 1

13325 J. Nicholas and H. H. Fanshawe. See Class X.

13420 E. L Mayer, London. Improvements in elements or electrodes for electric batteries. October 4

13440 G. Zanni, London. Improvements in electric batteries. October 4

13611 T. Coad and H. V. Coad, London. Improvements in voltaic or electric batteries. October 8

13722 C. E. Ponder, J. MacGregor, and P. Harris, London. An improvement in electrical secondary batteries. Complete specification. October 10

13805 H. M. Musgrove and H. Lyon, Glasgow. Improvements in electric batteries. October 12

13890 D. Urquhart, London. Improvements in or connected with electric batteries. October 13

13903 R. Kennedy, Glasgow. Improvements in and relating to thermo-electric generators. October 13

14021 N. de Benardos, London. Improvements in secondary batteries or electrical accumulators. October 15

14051 D. G. Fitzgerald. See Class X.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12778 S. F. Walker. Dynamo-electric machinery. October 8.

13987 J. G. Statter, S. L. Brunton, and J. W. Kempster. Collector or brush for dynamo or magneto-electric machines. September 21

14033 C. D. Abel—From Siemens and Halske. An improvement in electrolysis. September 28

14286 A. Wunderlich and O. Eisele. A Galvanic battery. October 8

16151 W. Webster, jun. Primary voltaic batteries, and preparation of the elements and solutions employed therein. October 12

16823 E. Barbier and M. Leclanché. Electrical batteries, and depolarising bodies to be used therein. September 21

17056 G. Kapp. Dynamo-electric machines. September 28

1887.

3719 M. Kotyra. See Class I.

4311 H. H. Lake—From A. W. Meserole. Secondary batteries. October 5

7079 E. Wilson. Dynamo-electrical machines. September 28.

7975 L. C. E. Liebez. Secondary batteries. October 8

9104 A. P. Trotter, H. W. Ravenshaw, and W. T. Goolden. Dynamo electric generators and motors. October 12

11917 R. Kennedy. Continuous current dynamo-electric machines and electro-motors. October 5

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

12712 G. Mills and G. H. May, Glasgow. Improvements in machinery for manufacturing paper. September 20

12762 P. E. E. Pesier, London. Improvements in treating vegetable materials to fit them for the manufacture of paper, pasteboard, threads, tow, or other like objects. September 20

12903 A. Wright, Glasgow. Improvements in the manufacture of paper pulp. September 23

12917 C. Beadle, London. A new or improved method of treating or preparing paper for the manufacture of paper bags and other envelopes therefrom, and for other purposes. September 23

13255 A. B. Warhurst, Manchester. Improved paper for toilet and other purposes. September 30

13792 J. Robertson, Manchester. Improvements in the manufacture of paper from Esparto straw or other material, and in the arrangement of machinery or apparatus employed for such purposes. October 12

13926 A. Schleipen, Paris. Improved process and machinery for the treatment of peat used in the manufacture of paper pulp, also applicable to the washing of the raw material for the manufacture of paper pulp generally. October 14

14034 E. Casper, London. Improvements in treating the barks of rhea or China grass and like plants, and apparatus therefor. Complete specification. October 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15856 H. Blackman. Disintegrating fibrous substances, and manufacturing paper pulp, and apparatus therefor.

1887.

11610 J. E. Warren and F. A. Cloudman. Apparatus for effecting the recovery of chemicals from spent liquors of pulp digesters. October 1

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

APPLICATIONS.

13196 W. P. Thompson — From F. Kleeman, Germany. Improvements in the purification of extracts or juices from fruits, roots, malt, and other vegetable matters, and of juices from maltose. Complete specification. September 29

13277 F. Nettlefold, London. The synthetical or artificial production of quinine or body of the chemical composition of quinine. September 30

13693 G. Trier, London — From C. R. Poulsen, Denmark. Apparatus for producing ozone. October 10

13839 A. G. Salamon, London. Improvements in the treatment of benzoyl sulphonic amide, commonly known as "saccharine." October 12

COMPLETE SPECIFICATION ACCEPTED.

1886.

15175 J. C. Mewburn—From L. Leilliard. Manufacture of ozone and apparatus therefor, and application of ozone to the purification of alcoholic liquids, etc. October 5

XXI.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

12735 D. Grünfeld and H. J. Schumann, London. The manufacture of "repeating matches." Complete specification. September 20

13029 T. Nordenfelt, London. Improvements in fuses for projectiles. September 26

13541 J. Cope, Sheffield. Improvements in fog signals for railways. October 6

13730 T. G. Hart, London. Improvements in explosives for use in firearms. October 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

10580 D. Johnson and W. D. Borland. Ammunition. Oct. 19.

15993 A. W. Conquist and C. O. Lundholm. See Class X.

16595 W. H. Noble. Manufacture of gunpowder and charges for guns. October 19

16656 H. E. Newton—From A. Nobel. Explosives, and use of same, especially shells and torpedoes. October 19

1887.

418 E. Edwards—From R. Sjoberg. A new explosive. September 28

10655 E. Turpin. Production of explosives. September 28

10667 E. Turpin. Explosives. September 28

Printed and Published by EMMOTT & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.
LONDON OFFICE, for the Sale of Copies and Receipt of Subscriptions: 6, York Street, Covent Garden

THE JOURNAL
OF THE
Society of Chemical Industry:
A MONTHLY RECORD
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 11.—Vol. VI. NOVEMBER 30, 1887. Non-Members 30/- per annum; Members 21/- per Set; Single Copies 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.

COUNCIL FOR YEAR ENDING JULY, 1888.

President: Prof. James Dewar, F.R.S.

Vice-Presidents:

Prof. F. Clowes, D.Sc.
Sir J. Neilson Cuthbertson.
David Howard.
Dr. Ferdinand Hurter.
Ivan Levinstein.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
Prof. W. A. Tilden, F.R.S.
John Williams.
Philip J. Worsley.

Ordinary Members of Council:

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J. Rowan.
Dr. Edwd. Schunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

With Sixteen Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, 20, Avenue Road, Regent's Park, N.W.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

NOTICES.

Notice is hereby given that the numbers for January 1882, 1883, and 1886, and February, 1886, are exhausted, and no orders for those copies can be executed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January, 1882 and 1883, at the following prices:—January, 1882, 5s.; January, 1883, 2s. 6d. Members possessing odd copies of these numbers are particularly requested to communicate at once with Mr. Cresswell.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

Members are requested to note that the subscription of 25s. for 1888 falls due on the 1st January next. Cheques and orders should be made payable to the Honorary Treasurer, Mr. E. Rider Cook, and forwarded either to him, at Bow, or to the General Secretary. Until payment is made members are not entitled to the Society's Proceedings, under Rule 29 of the Bye-Laws.

CHANGES OF ADDRESS.

Jno. Charlton; Journals, etc., to 42, Blackfriars Street, Manchester, instead of to "Ellesmere Park, Eccles," as erroneously given in printed register.

E. Cleminshaw, l/o Birmingham; Belvedere, Kent.

Jas. Cockburn, l/o Heathcote Street; 43, Camden Square, N.W.

E. C. Conrad, l/o Wellclose Square; Paraparap, Portland Road, Gravesend, Kent.

H. B. Giboins, l/o Cheltenham; Holly Lawn, Beechen Cliff, Bath.

P. S. Gilchrist, l/o Goole; c/o Orient Guano Co., Orient, N.Y., U.S.A.

G. J. Hamlen, l/o Willowbank Crescent; 162, St. Vincent Street, Glasgow.

J. F. Ingleby, l/o Carlton Terrace; The Park, Hull.

Dr. Wm. Johnstone; Journals, etc., to City Central Laboratory, 13, Fish Street Hill, E.C.

J. J. Knight, l/o Birmingham; Lestiford Mill, Wonersh Guildford.

F. Maxwell Lyte, l/o Putney; 60, Finborough Road, Redcliffe Square, S.W.

J. B. McArthur, l/o Midcalder; 11, Haile Street, Edinburgh

G. D. Macindoe, l/o Wolverhampton; Hall's House, North Woolwich Road, Victoria Docks, E.

T. R. Marshall, l/o Munich; bei Frau Reinhold, 4, Spitalstrasse, Erlangen, Bavaria.

Jno. Morrison, l/o Box 74; P.O. Box 336, North Adams, Mass., U.S.A.

Wm. Pringle, l/o London; Laboratory, Mercara, Coorg, South India.

Jno. Riley, l/o Fairfield; Mayfield, Castleton, near Manchester.

R. Wightwick Roberts, l/o London; 22, Calle Arturo Prat, Valparaiso, Chili.

W. Johnston Saint, l/o Aberdeen; bei die Frau Pfarrer Kern, 13, Friedrichstrasse, Erlangen, Bavaria.

C. Sevin; Journals (temp.) to c/o Dollman & Pritchard, 3, Lawrence Pountney Hill, E.C.

F. P. Stiker, l/o High Street; 453, Fourteenth Street, Buffalo, N.Y., U.S.A.

J. F. Tristram, l/o Northwich; 622, Stockport Road, Manchester.

P. H. Walsh, l/o Blackburn; c/o Proctor & Gamble, Soap Factory, Ivorydale, Ohio, U.S.A.

M. W. Wiley, l/o Bell Terrace; Billsdale House, York Road, West Hartlepool.

W. H. Wood, l/o London; 15, Church Place, Hopwood Lane, Halifax.

LIST OF MEMBERS ELECTED, 25th NOVEMBER, 1887.

J. J. Candlish, Bottle Works, Seaham Harbour, Co. Durham, glass manufacturer.

Jas. P. Cornett, Ford Paper Works, Hylton, near Sunderland, paper manufacturer.

Thos. M. Drown, Mass. Inst. of Technology, Boston, Mass., U.S.A., professor of analytical chemistry.

David R. Hamilton, 19, Graham Street, Bridgeton, Glasgow, dyer.

Dr. F. Stanley Kipping, 13, Lonsdale Terrace, West Meadows, Edinburgh, chemist.

Dr. L. Limpach, 20, St. Mary's Road, Crampsall, Manchester, chemist.

Wm. A. McGubbin, The Elms, West Derby, Liverpool, chemical student.

Sydney Martineau, South Road, Clapham Park, S.W., analyst in sugar refinery.

Gideon Pott, c/o Watson, Laidlaw and Co., Kingston, Glasgow, engineer.

Daniel W. Rogers, Hadley, Mass., U.S.A., master of Hopkins Academy.

W. Lascelles Scott, Chemical and Physical Laboratories, Forest Gate, E., chemical engineer.

Dr. J. A. Voelcker, Royal Agricultural Society of England, 12, Hanover Square, W., consulting chemist

And. Wallace, 15, Abbey Street, Paisley, N.B., dyer.

Death.

Thos. Routledge, Claxheugh, Hylton, near Sunderland.

Communication.

REPORT ON SECTION III. OF THE MANCHESTER ROYAL JUBILEE EXHIBITION:

THE CHEMICAL AND ALLIED INDUSTRIES.

BY WATSON SMITH,

Lecturer in Chemical Technology in the Victoria University, etc.

(Continued from p. 643.)

GROUP VIII.—METALLURGY.

The Abram Coal Co., Bickershaw, Wigan (No. 799).—This firm shows, among specimens of *Gas Coals,* the Abram new boghead cannel, giving gas of high illuminating power; selected cannel chippings, washed cannel nuts and Arley gas coal. This latter coal gives gas of high illuminating power, and furnishes, it is said, a good yield of residual products. Specimens are also shown of Wigan 4ft., 5ft. and 6ft. gas coals.

As regards *House Coals,* there are the best Arley coal, one of the best house coals in the district; Orrell 5ft. coal and Abram Main coal. These are raised from depths varying from 300 to 650 yards. A peculiarity with respect to the cannel is that it occurs in the *middle* of the Wigan 4ft. mine, and is much thicker than at any other colliery in the district.

The Astley and Tyldesley Coal and Salt Co., Limited, near Manchester (No. 813).—The specimens shown are blocks of the following:—"Astley," best house coal; "Hartley," house and steam coal; "Six Feet Rams," steam coal; "Crombouke" coal and Great Seven Feet coal.

The two latter blocks give sections of the upper part of the seams referred to, just as when taken from the mine at a depth of about 340yds. from the surface.

Platt Brothers & Co., Limited, Oldham (No. 806)—Specimens of "Big Mine" coal for house-fire purposes, very clean and hot, with a minimum of ash. It is obtained from Moston Colliery, Failsworth, near Manchester. Calcined shale is also shown, for carriage drives, footpaths and garden walks, as well as close-fire bricks made from pit shale and clay ground together and passed through two pairs of rollers obtained from materials from the same colliery. Very good specimens of machine-made facing bricks and ornamental bricks are exhibited. Specimens of Mountain Mine coal, from the Jubilee Colliery, Shaw, near Oldham, are also shown:—(1) For house-fire purposes, slow-burning and clean in use; (2) washed smithy coal for weldings; and (3) hard coke, made from Mountain Mine slacks, ground and washed, and containing carbon 93·23, sulphur 0·77, moisture 0·79 and ash 5·21 per cent.

Statistics of Coal Trade.

The approximate annual output of coal is about 160 million tons, and the value at the pits about 43 millions sterling. The output of coal reached its maximum in 1883, when the quantity raised was 163,737,000 tons. Since this date the amount raised each year has declined, that for 1885 (the most recent year for which statistics are available) being 159,351,418 tons, and it is said the quantity for 1886 will only be about 158,000,000 tons. The value has also decreased in the same period from about £45,000,000 to £42,500,000.

Percy C. Gilchrist, Palace Chambers, Bridge Street, Westminster, S.W.—The specimens exhibited illustrate the basic material used in the converter or open-hearth furnace, the phosphoric pig used, the lime used during the process and the steel made, showing some of the uses to which it has been applied; finally, the slag, both as made and as ground ready for use as a manure.

Prior to 1879 it was believed that intense heat was the obstacle that prevented the elimination of phosphorus in the Bessemer and open-hearth processes. The Basic or Thomas-Gilchrist process, introduced in 1879, proved that excellent steel could be commercially made from phosphoric pig by simply changing the lining in the converter and open-hearth furnace from a silicious—*i.e.*, acid one, to a lime—*i.e.*, basic one, and by adding some 2cwt. to 4cwt. of lime for each ton of pig treated. In other words, these processes, instead of being conducted so that the slag produced with the steel contained over 60 per cent. of silica and traces of lime, were conducted so that the slag produced contained, roughly, 6 per cent. of silica and 50 per cent. of lime and magnesia ; under the former (acid) conditions the steel contained rather more phosphorus than the pig from which it was made ; and under the new (basic) conditions the steel only contains 3 per cent. of the phosphorus in the pig treated.

The lime lining in general use is made by roasting or igniting limestone (preferably magnesian limestone) at a very intense heat, by which means the limestone becomes reduced in weight and bulk to one-half of its previous weight and bulk, and also becomes intensely hard. This material is ground and made plastic by admixture with boiled tar, and the resulting material put into place by ramming; or it is used in the form of bricks made under a very considerable pressure ; the object of this basic lining being to allow of the production and retention of a lime (*i.e.*, basic) slag. The 2cwt. to 4cwt. of lime used per ton of pig treated consist of ordinary lime as free from silica as possible, the function being to produce a limey slag capable of absorbing the phosphoric acid produced by the oxidation of the phosphorus in the pig treated.

The pig used contains :—

Silicon	0·2 to 1·5	per cent.
Sulphur	trace to 0·15	,,
Phosphorus	0·08 to 3·2	,,
Manganese	0·5 to 2·0	,,

The steel made contains :—

Silicon	trace.		
Sulphur	trace to 0·08	per cent.	
Phosphorus	0·002 to 0·08	,,	
Manganese	0·1 to 0·5	,,	
Carbon	0·08 to 0·5	,,	as required.

The slag made contains 97 per cent. of the phosphorus in the pig treated, averaging :—

Phosphoric acid	17	per cent. to 20 per cent.
Lime	50	,,
Magnesia	4	,,
Silica	8	,,
Oxide of iron	14	,,
Oxide of manganese	5	,,
Alumina	2	,,

This slag, ground to an almost impalpable powder, has been proved to be a valuable manure, giving the best results on sandy, peaty and loamy soils, and is now becoming generally known as a valuable fertiliser.

The production of basic steel has been :—

	England	Other Countries.	Totals.
12 Months ending 30th Sept. 1878	20	—	20
,, ,, ,, ,, 1879	1,150	50	1,200

,, ,, ,, 31st Dec. 1886	277,259	1,097,758	1,375,017
	891,000	3,764,927	4,655,927

In 1886 some 1,650,000 tons of pig, scrap and ferro-manganese were employed ; 171,000 tons of limestone for lining ; and 240,000 tons of lime for additions—producing some 1,375,000 tons of ingots of the value of £4,125,000, and 412,500 tons of slag of the value of £412,500.

Before the introduction of this process one-tenth only of all the iron ores in Europe was available for steel-making, owing to their containing too much phosphorus, and owing to the fact that no phosphorus is eliminated in the processes of steel-making then practised. By this process the remaining nine-tenths can be made into excellent steel, the phosphorus at the same time being converted into a phosphate of lime, easily assimilated by plants.

THE COLLEGE OF AGRICULTURE, Downton, near Salisbury (No. 812), illustrates in a series of interesting specimens the experiments and researches of Dr. Munro on the utilisation of basic slag for manurial purposes, as already referred to in the last-named exhibit. A chart is shown indicating the effects of basic cinder used as a fertiliser. (See this Journal, 1886, pp. 104, 433, 464, 610 and 611.)

THE MOSTYN COAL AND IRON Co., North Wales (No. 809), exhibits specimens of spiegeleisen, ferro-manganese, silico-spiegel, silicious iron, ferro-chromium, and also samples of manganese, whilst the WEST CUMBERLAND IRON AND STEEL Co., LIMITED (No. 811), shows specimens of material and products illustrative of the manufacture of Bessemer pig iron, steel rails, plates and steel castings.

MESSRS. CARRICK & BROCKBANK, Pall Mall, Manchester (No. 730), show a beautiful model of Gjers, Mills & Co.'s Ayresome Iron Works, Middlesbrough, and a case containing samples of Ayresome foundry iron and hematite iron, with ferro-silicon and silico-spiegel.

MESSRS. JOHNSON, MATTHEY & Co., Hatton Garden, London (No. 802).—Platinum in the form of apparatus for the concentration of sulphuric acid, etc., is shown to the value of £3000. Glass is gradually giving way to platinum for the purpose of concentrating sulphuric acid. In German vitriol works these stills are of much more frequent occurrence than in English factories. Even in the comparatively small Swiss factory of Gebrüder Schnorf, of Uetikon, near Zürich, referred to by Lunge in his book on the Alkali Manufacture as amongst the first to adopt Malètra's smalls kiln, there are two such platinum stills in operation. An interesting feature is the standard metre in irido-platinum, and of great value.

JAMES SMITH, 39 and 41, Bridge Street, Manchester (No. 803).—The process of manufacturing gold leaf is here seen in practical operation. In beating out the leaf a peculiar method of administering the blow with the mallet is necessary, one in which a certain forward movement of the whole body appears to be involved. This is one of the most popular exhibits in the section.

THE MAGNESIUM METAL Co., Patricroft, near Manchester (No. 804).—Prominent in this exhibit are very fine specimens of the ores of the metals antimony, bismuth, magnesium, mercury, potassium, sodium, vanadium, also silver and gold, with beautiful specimens of each of these metals. One of the ingots of antimony is perhaps the largest specimen ever exhibited. On its surface is distinctly seen the beautiful fern-like or "star" crystallisation that characterises this metal when pure ; hence its technical name, "Star Antimony." One of the specimens of bismuth shows the beautiful crystals, Grecian key-like in pattern, that characterise this peculiar metal. Magnesium is seen in the various forms in which it is produced for the market, such as ribbon, wire, ingots and powder. Possibly the finest specimen of quicksilver ore existent in the world may be seen in this case. This magnesium company is the only firm in the kingdom which distils mercury from its ore or matrix. A fine specimen of metallic sodium is exhibited. Attention may also be called to the splendid exhibit of "silver cake," which weighs some 8000 ounces, and to a valuable specimen of auriferous or gold quartz from the Sheba Reef, in the Transvaal.

The ore is found to average from five to seven ounces of gold to the ton. Immediately beneath this auriferous quartz may be seen a small bottle of pure gold, the actual product of one ton of this ore. Adjoining will be found some quartz in which the gold is visible. In addition to the precious metals, this firm exhibits a variety of chemicals. Amongst these we may mention sodium chlorate, crystallised; an article first introduced by the Magnesium Company, and which is now manufactured on a fairly large scale. Here also may be seen large specimens of salts of vanadium. The oxide of vanadium exhibited is a portion of the first specimen ever produced, and was shown a few years ago by Sir Henry Roscoe at a lecture delivered by him on "Vanadium" at the Royal Institution, London, as one of the greatest chemical novelties of that year. The specimens of Senarmontite crystals, one of the oxides of the metal antimony, will be very interesting to mineralogists. The fine specimens of crystallised sodium and potassium have attracted much attention. With this firm, whose exhibits denote much skill and scientific enterprise, the name of its director, Mr. Samuel Mellor, is intimately connected.

Joseph Walker Parker & Co., Lead Works, Chester (No. 805).—This firm has long been noted for its sheet lead, termed "chemical lead," supplied to sulphuric acid manufacturers for their vitriol chambers. Red lead, and red lead for the use of glassmakers; flake and powdered litharge, also flake litharge specially refined for varnish manufacturers; orange lead, and sublimed lead made from lead fumes, are represented. Laminated lead for damp walls, and all kinds of sheet lead; water piping, gas piping, lead pipe tinned inside, and pure and block tin pipe, offer considerable interest. Specimens of patent shot and hard shot, and also lead bullets, are shown. Special stress is laid on the dry white lead ground in oil, and the oval lead piping for resisting the action of frost.

Henry Wiggin & Co., 55, George Street, Birmingham (No. 810).—Specimens illustrating the manufacture of nickel and cobalt, from the raw material to the finished product, are shown. As raw materials, samples of nickeliferous pyrites from Norway, double silicates of nickel and magnesium from New Caledonia, arsenical nickel and cobalt from Hungary, and manganiferous cobalt ore from New Caledonia, are shown. The metals termed speiss or regulus, obtained in the smelting of these ores, and their ultimate solutions from which the iron, copper, etc., are separated by precipitation or otherwise, form an interesting feature. The nickel and cobalt are precipitated by a process applied by Mr. Chas. Askin, the originator of the firm, as hydrated oxides. The nickel oxide is then converted into metal for the manufacture of German silver and other white alloys, whilst the cobalt obtained in the form of various oxides is used for producing blues on earthenware, porcelain, and glass. Specimens of all these are shown, together with pure nickel oxide and metal in cubes and grains; also, an alloy containing respectively 50 per cent. of copper and of nickel, for casting purposes; and an ingot of German silver ready for rolling, as well as all kinds of utensils. Specimens of refined black cobalt oxide, cobaltous oxide, silicate of cobalt (printing blue), red silicate and carbonate of cobalt, and a handsome plaque illustrating the way in which various shades of cobalt may be produced upon china. Nickel and cobalt occurring in many complicated minerals containing sulphur, arsenic, iron, copper, antimony, bismuth, tin, lead and various earthy matters, all of which require to be separated by smelting or wet processes. Various by-products obtained in these processes are exhibited. Amongst specialities in the form of white alloys is Wiggins's registered metal "Silveroid," used largely for harness furniture, railway carriage fittings, steamship and lavatory fittings, etc. This alloy possesses the whiteness of silver, and does not become tarnished under ordinary conditions. The patent rolled nickel and cobalt, used specially for anodes in the processes of nickel and cobalt plating, and also a variety of cast and wrought anodes, are shown. As regards the ores, much of the nickel ore does not contain more than 2 per cent. of the metal, whilst the richest specimens obtained from Hungary are found with 15 per cent., and also 5 or 6 per cent. of cobalt. Nickel is at present very low in price—about 2s. per lb.; a few years ago it was as high as 16s. per lb. The introduction of nickel as the means of whitening and coating copper has proved of the greatest value, and thus the extensive and important industry of electroplating with it has been built up.

Webster's Patent Aluminium Crown Metal Co., St. Mary Axe, London, E.C. (No. 807).—Aluminium is very light, and also capable of receiving a high polish; does not easily tarnish, and gives out a clear and beautiful ring when struck. It is, therefore, not surprising that inventors have paid it great attention. In the handsome show-case of this firm are exhibited articles illustrating the manufacture of aluminium and its alloys. As a raw material, a specimen of the chloride is shown, and also a large button of aluminium as reduced in the matrix in which it was formed; pure aluminium in pig, etc.; and various forms of alloys as applied to the requirements of the different industries.

Duncan McKechnie, St. Helens, Lancashire (No. 808).—The wet process of copper extraction is here illustrated, and among the specimens of materials and products shown are Rio Tinto Spanish pyrites, burnt Spanish pyrites, purple ore, lead precipitate, silver precipitate and copper precipitate. These are worked up to the production chiefly of refined ingot copper, refined bar silver and pig lead, specimens of which are exhibited. The manufacture of sulphate of copper as a branch of the foregoing is illustrated as to material and product by specimens of argentiferous and auriferous shot copper, sulphuric acid, sulphate of copper and silver residue.

Wet Process of Copper Extraction.—This process is used in the extraction of copper from the burnt cupreous pyrites used in the vitriol manufacture. The process, as worked, is generally designated Henderson's, but the idea was first worked out by Mr. Longmaid. In 1842 he took out a patent for "Improvements in treating ores and minerals, and in obtaining various products therefrom, certain parts of which improvements are applicable to the manufacture of alkali." This consisted in calcining pyrites with sodium chloride at a low red heat, lixiviating, precipitating the copper with iron and evaporating the liquor down to obtain crystals of sodium sulphate. This process was worked at St. Helens for some time, but was abandoned in 1862. Mr. Henderson's process incorporated in a more or less modified form Longmaid's ideas, but to the former must be ascribed the credit of first recognising the suitability of burnt Spanish pyrites for this method of treatment. Various kinds of furnaces have been in use in calcining the ore with sodium chloride. In Longmaid's process the ore was calcined in an open reverberatory furnace. There have also been employed long open furnaces fired by gas, furnaces in which an arch extended from the bridge half over the bed, thus protecting the ore nearest the bridge from too intense a heat. Mr. Gibb patented a mechanical furnace with revolving hearth, which was used at the Bede Metal Company's Works, Newcastle-on-Tyne, but has a long time been abandoned, and now the furnace in general use since 1872 is the blind roaster, or muffle furnace.

The mixture of burnt ore and salt is calcined until the copper is converted into soluble cupric chloride. It is then lixiviated in vats containing about 14 tons of ore, with water alone, and later on with acidulated water, which removes the copper, silver and lead, leaving the oxide of iron, called "purple ore," behind in the vat. The first three washes contain 95 per cent. of the silver, which is recovered by Claudet's process. In this process a precipitation with a soluble iodide is adopted. The resulting silver iodide is decomposed with zinc, and the zinc iodide then used to precipitate more silver. The silver precipitate obtained is smelted into argentiferous pig lead, which is then cupelled, and the silver cast into bars. The cupric liquor, after desilverisation, is run into tanks containing scrap iron, and boiled until all the copper is precipitated as metallic copper: this, after washing and sieving, is either smelted and refined by itself, or along with the produce of other ores, into cake or ingot copper. The purple ore, or oxide of iron, is sold either in the fine state, for "fettling" puddling furnaces, or made into blocks for the blast furnaces. The lead precipitate is smelted in the Cornish furnace into pig lead.

Sulphate of Copper Manufacture.—This salt was at one time chiefly prepared as a by-product in silver smelting works. In argentiferous copper mattes obtained from these works the copper and silver were separated by means of sulphuric acid, the liquor obtained being run into leaden tanks, and copper sulphate crystallised therefrom. The silver and gold were left undissolved by the acid. Owing to the increasing demand for copper sulphate, and this source not being sufficiently productive, special works are now engaged in its manufacture.

Wet Copper Extraction.—Quantities of the above metals extracted in Great Britain during 1884, 1885, and 1886:—

	Burnt Ore. Tons.	Metallic Cu extracted. Tons.	Extracted by Claudet's Process.	
			Gold. Ounces.	Silver. Ounces.
1884	416,412	15,200	1900	335,000
1885	407,700	11,880	1810	328,000
1886	393,699	13,799	1780	316,928

About one-eighth part of this ore is treated at the exhibitor's works.

Sulphate of Copper.—The quantity manufactured is about 16,000 tons, of which about one-sixth is produced at the exhibitor's works.

GROUP IX.—ALKALIS, ACIDS AND SALTS.

JOHN RILEY & SONS, Hapton Chemical Works, near Accrington (No. 814).—This firm makes a special feature of pure sulphuric acid produced from brimstone and concentrated in platinum. This pure acid is much in request for dissolving indigo, to form the sulphonic acid, as well as for the preparation of white and pure sulphate of ammonia.

A soda ash (Leblanc process), which has undergone special refinement for the purposes of the calico printer, is also a speciality. It is an article free from insoluble matter, iron, etc., and which can be used by bleachers without fear of iron stains, etc., in the cloth after bleaching, so detrimental to the colours used in printing and dyeing. In obtaining such a soda ash, besides special purifying processes, a system of mechanical furnaces, heated by coal-gas, is adopted. For the wool scourers a pure and highly carbonated ash, free from hydrate, is made. Stannate of soda, made by Riley's patent process, and in a very pure state, is exhibited. It is used as a mordant by calico printers, dyers, etc. Ferrous sulphate ("copperas") as used in black dyeing and for preparing the indigo vat; and also ferrous and ferric chlorides, as used by dyers and papermakers. Copper sulphate and nitrate, tin crystals (crystallised stannous chloride), and also acetate and nitrate of tin, likewise serving as mordants, are exhibited, as prepared for mordanting purposes.

Zinc chloride is largely used by the Lancashire cotton merchants in the sizing of their goods, to prevent the starch of the size from contracting mildew. It is made in the pure state and liquid form for home consumption, but solid for export. Sulphate of zinc is also used for antiseptic purposes. Besides these, alizarin oil and oleine oils are specialities, as well as a series of chemicals made for the use of indiarubber manufacturers, of whom there are a great many in the Manchester and Salford districts.

GASKELL, DEACON & CO. (No. 815).—The chief articles exhibited are bleaching powder, bicarbonate of soda, crystal carbonate, calcium chloride, soda ash of 30 per cent. and 58 per cent. of Na_2O, refined alkali at 30 and 58 per cent., cream caustic at 60 per cent., and white caustic at 60 and 70 per cent. Also a fine block of soda crystals under a glass shade.

Crystal Carbonate.—For an account of this valuable salt the reader is referred to the report on the chemical exhibits in the International Inventions Exhibition of 1885. (This Journal, 1885, p. 523.)

Bicarbonate of Soda.—From the crystal carbonate, itself a very pure article, a fine high strength bicarbonate is made which, on analysis, gives the following numbers:—Bicarbonate of soda, 99·48; monocarbonate, 0·33; sulphate, *nil*; chloride, 0·05; magnesium chloride, *nil*; moisture, 0·10; insoluble, *nil*; total = 99·96.

The full account of the improved processes of manufacture patented by this firm will be found in Mr. Muspratt's address to the Society of Chemical Industry. (This Journal, vol. **5**, p. 401; also vol. **4**, pp. 523 and 524.)

WIGG BROS. & STEELE, Old Quay, Runcorn (No. 817).—This firm exhibits specimens illustrating the manufacture of sulphuric and other acids, salt cake, copper by the wet process, pearl hardening, bleaching powder and paints, with the raw materials used.

MESSRS. JOSIAS C. GAMBLE & SON, Gerrard's Bridge Chemical Works, St. Helens (No. 819).—The name of Col. Gamble will always be closely associated with the history and development of the Leblanc alkali industry. It was in the works of this firm that

Weldon first discovered the true conditions on which depends the success of the Weldon process for recovering peroxide of manganese from the otherwise waste still-liquors.

Besides the usual products of the alkali maker in an alkali-making district, this firm shows the following specialities of interest :—

Sulphide of sodium, in crystals, and of the formula $Na_2S + 9H_2O$, made by Schaffner and Helbig's patent process, pure chlorate of sodium, made by Pechiney's patent process, the same in small crystals, pure chlorate of barium in crystals, and of the formula $Ba(ClO_3)_2 + H_2O$, barium chlorate (pure) in powder, chlorate of strontium (pure) $Sr(ClO_3)_2$, sodium hypochlorite $NaClO$, potassium hypochlorite $KClO$, aluminium hypochlorite $Al_2(ClO)_6$, chloric acid $HClO_3$, calcium chlorate $Ca(ClO_3)_2$, ammonium chlorate NH_4ClO^3, aluminium chlorate $Al_2(ClO_3)_6$, Pearl hardening.

TENNANTS & Co., Mill Street, Clayton, Manchester (No. 818).—Like most of the alkali makers in the Manchester district, this firm has grafted on to the usual products of the Leblanc alkali industry, those used by the dyer, calico printer and bleacher. Since it may be interesting to other alkali makers not resident in a district the prevailing industries of which are so largely those devoted to dyeing and calico printing, the list of exhibits shown by Tennants & Co. is given :—

Iron.	Tin.	Sodium.	Potassium.	Zinc.
Ferrous chloride	Stannate of soda	Sodium bisulphite	(Acid potassium sulphate)	Zinc chloride
Ferric chloride	Stannous chloride (tin crystals)	Sodium sulphate (Glauber salts)	(Potassium bichromate	Zinc sulphate
Ferrous sulphate	Stannic chloride	Sodium bichromate (dry)	Red and yellow Prussiates of potash	—
Ferric sulphate	Tin nitro-muriate	Sodium bichromate (Crystals)	—	—
—	Tin oxymuriate	—	—	—
—	Tin acetate	—	—	—

Magnesium.	Manganese.	Copper.	Acids.	Calcium.
Magnesium sulphate (Epsoms)	Precipitated pure Peroxide of Manganese	Copper sulphate	Rectified oil of vitriol	Calcium bisulphate
Magnesium carbonate	Manganese chloride	Coppor nitrate	Brown oil of vitriol	—
Magaesito	Manganese carbonato	—	Hydrochloric acid	—
—	—	—	Aquafortis (com)	—
—	—	—	Aquafortis (pure)	—

JAMES MUSPRATT & SONS, Liverpool and Widnes (No. 820).—James Muspratt was the founder of the South Lancashire Alkali Industry, and any exhibition of chemical products would be incomplete without being represented by so historic a firm.

The specialities illustrated in the examples shown are sulphur recovered from alkali waste by Mond's process, manganate of soda, chlorates of potash and soda, produced by Messrs. Muspratt and Eschellmann's process, together with the materials and by-products. (See this Journal, 1885, p. 524.)

Barium Products.—Barium sulphide, zinc sulphide, blanc fixe, barium chloride and hydrate.

A. G. KURTZ & Co., Sutton Alkali Works, St. Helens, Lancashire (No. 825).—The manufactures of this old-established firm are chiefly confined to salt cake designed for alkali and glass making, caustic soda, chlorate of potash, bleaching powder, soda ash and soda crystals.

THE WIDNES ALKALI Co., Limited, Widnes, Lancashire (No. 830).—*Articles exhibited.*—Caustic soda, 76, 74, 72, 70, 64, and 60 per cent. white ; chlorate of potash in crystals, containing 99·98 per cent. of $KClO_3$, and extra fine ground ; chlorate of calcium in solution ; manganate of soda, the new disinfectant ; permanganate of soda, crude and in solution ; black ash or crude carbonate of soda ; sulphate of soda (salt cake) ; bleaching powder.

GENERAL STATISTICS OF THE ABOVE PRODUCTS OF THE ALKALI MANUFACTURER.

The manufacture of caustic soda has increased within the last twenty-two years from about 100 tons per week to about 3000 tons per week.

Caustic Soda is chiefly used by paper makers, and in the manufacture of soap ; but it has also a considerable application for various other purposes. Its selling value in 1865 was £13 per ton for 60 per cent., in 1873, £22 to £24, and the price has now declined to £7 per ton.

Manganate of Soda has been recently developed on a manufacturing scale for the deodorisation of sewage, and as a disinfectant.

The total weights of caustic soda and bleaching powder made for the year 1886, were :—

Caustic Soda : 153,884 tons.

Bleaching Powder : 136,234 tons.

The return of the exports to foreign countries for the year 1886, was :—

Alkali, including Caustic Soda, Soda Ash, Bicarbonate, Crystals, etc. : 284,634 tons, at a value of £1,609,484.

Bleaching Powder : 77,524 tons, value £503,000.

The annual consumption of raw materials for the above, which merely include the two chief export centres, and two articles out of the numerous products of the alkali trade, will be about :—

1,423,465	tons of fuel.
394,742	,, ,, pyrites.
713,112	,, ,, salt.
234,493	,, ,, lime.
134,619	,, ,, limestone.

The trade also employs some thousands of work-people, and a surrounding of dependent trades for machinery, packages, etc., etc.

The value of chemicals (with the exception of bleaching powder, which is supported by a combination of manufacturers) has been reduced about one half during the last ten years.

THE GREENBANK ALKALI WORKS Co, LIMITED, ST. HELENS, LANCASHIRE (No. 831). — This firm acquired many years ago a high reputation, both in this country, the Continent and America, for a very pure and high-strength caustic soda, and it was, the writer believes, the first to put in the market a 76 per cent. caustic soda. The improvements introduced into the various processes which mainly led to the production of this high-strength caustic, as well as increased yields of chlorate of a superior quality, in the operations involved in that branch of manufacture, were mainly the work of the late Mr. W. H. Balmain, the former manager, whose name is historically connected with the development and improvement of the Leblanc soda industry in South Lancashire.

The specialities exhibited may be enumerated as doubly-refined caustic soda, and the same in powdered form for bleachers, dyers, etc., and for making hard soap; pure caustic potash for woollen manufacturers, and for making pure potash soaps; refined pearl ashes: chlorate of potash in crystal and powder; bleaching powder; pure red oxide of iron and oxide paint.

John Thom, Birkacre, Chorley, Lancashire (No. 824).—This exhibit is of great historic interest, being a faithful representation in model form of the simple apparatus which Mr. John Thom, now for many years a citizen of Manchester, though originally hailing from the neighbourhood of Glasgow, constructed in 1836 for making soda by the ammonia process. Mr. Thom was the original discoverer of the simple reaction between sesquicarbonate, or otherwise bicarbonate of ammonia and sodium chloride, which forms the essential principle of the ammonia soda process. He was the first who made paraffin wax as a commercial article, obtaining the paraffin, however, from wood-tar by Reichenbach's process. He made small candles with this paraffin so obtained. Moreover, Mr. Thom was the first to manufacture artificial manures containing ammoniacal salts; he was actually the founder of the artificial manure industry. This work was accomplished in a chemical factory at Camlachie, near Glasgow, belonging to Messrs. Turnbull & Ramsay, in whose service he then occupied the position of chemist at the not too liberal salary of £30 per annum.

We have already referred to the fact that Dalton impressed penny ink-pots and soda-water bottles into his service in the pursuit of scientific research, but he was outdone by Thom in point of economy, the latter illustrating the reaction between sodium chloride and ammonium sesquicarbonate in apparatus simply composed of the hollow in the palm of one hand, using the finger of the other as a stirrer. I will use Mr. Thom's own words in a letter to his son:—"My first experiment was made by taking a good pinch of the substances (bicarbonate of ammonia and common salt), placing them in the palm of my left hand, mixing them with the forefinger of the right hand, and allowing water to drop from the fingers of my right hand to wash with as little water as possible. The heat of my hand dried very soon the product, and I learned that the decomposition could be made, whether profitably or not. This experiment done in the same way was shown by me to Professor Graham, the late Dr. Young, and many others, amongst whom I may mention Mr. William Henderson, of Glasgow—then a pupil of Graham's. After ascertaining that soda could be made in that way, I tried it in increasing quantities. I had no machinery in connection with it, except an old screw-press (model shown). I mixed the two salts in tubs (see models) and then placed the product in the till or burnt clay moulds, then used for refining or refined sugars. Later on, we substituted wooden ones of a similar shape, but larger. The soda was not crystallised by itself, but was dissolved with soda from other processes and crystallised in 500-gallon pans. It was considered better to carry this product from the ammonia soda process than put up dissolving, crystallising and draining apparatus specially for it." This latter statement, of course, means that so impure a soda would not bear the expenses alone of a sufficient purification, and hence it was mixed with the liquors of a stronger and purer Leblanc soda, and converted into soda crystals, relying upon the fact of formation of these crystals from a tolerably dilute solution, and the retention in the mother-liquors of the salt in excess and sal-ammoniac. The writer has received from Mr. William Henderson, of Glasgow, complete confirmation of Mr. Thom's statements, and he (Mr. Henderson) describes not only the experiments wrought in the palm of Mr. Thom's hand, but the apparatus for making larger quantities of the crude ammonia soda.

The following clause in a letter from Mr. Thom to the writer is worth quoting:—"When I left my employers," writes Mr. Thom, "I informed them that I did not think it advisable for them to continue this process, unless they got a chemist or someone who would feel interested in its success. I left them because I did not get paid enough. I had £30 a year for, I think, four years, and the attention required through bad joints, etc., etc., was very great. I left in 1838." Those, therefore, who feel disposed to institute any comparison between John Thom and Dyar and Hemming, to the disadvantage of the former, should reflect on the fearful disadvantages of Thom's situation, and that despite all these he still succeeded in passing from his crude laboratory performances to his equally crude manufacturing operations, and did succeed in putting ammonia soda in the market.

Some may be curious to know in what spirit he left such not very liberal employers. The account of the final episode deserves recital; it redounds to his credit, as it doubtless did to theirs—in quite another sense! As it was resolved to stop the process when Thom left, he "collected all the odds and ends with ammonia in them," to use his own words, "mixed them and all the urine on hand, with the charred siftings—that is, the charcoal not saleable from being too small—and with a lot of old animal charcoal which we had from the 'yellow prussiate' process and 'red liquor bottoms'—*i.e.*, the sulphate of lime resulting from making the 'red liquor' or aluminous mordant for calico printing, I took enough of the latter to at least fix all the ammonia in the lot. These were mixed in large heaps, many scores of tons, and I advised my employers to sell all as fertilisers. This mixture was tried in the Vale of Leven, Scotland, and in the West Indies, for sugar cane, by James Ewing, then M.P. for Glasgow. The result was astonishingly successful. Mr. Turnbull came up to Manchester to see how the stuff had been made, and tried to get me to go back to make more. I advised him to obtain slaughter-house offal, dead horses or cattle dying of disease, and place this material in a chamber where uncondensed muriatic acid gas could pass through, and continue the purchase of the urine of the neighbourhood (previously the material, bought at 3d. per ten gallons, for the ammonia soda process) along with the red liquor bottoms. He followed my instructions more or less, and laid the foundation of a most lucrative trade to him, and I believe, and the late Dr. R. Angus Smith believed, of the first manure works, of which there are now so many."

Messrs. Brunner, Mond & Co., Limited, Northwich, Cheshire (No. 816).—The description and general report given of the exhibit of this firm in the late Inventions Exhibition of 1885 (see this Journal, 1885, pp. 526 and 527), may be very well referred to in this case, with the statement that this exhibit in Manchester is, as regards specimens, show-case, and general appearance, incomparably finer than that in London. The specimens illustrate the Solvay ammonia-soda process, with the improvements introduced by Mr. Mond and other members of the firm. A specimen of bleaching powder made by Mond's recently patented processes is now to be seen—(this Journal, 1887, p. 140)—as also one of caustic soda, and another of a beautifully crystallised sesquicarbonate of soda, made by the process of Watts and Richards. This salt, which is crystallised in fine needles, is not a true sesquicarbonate, but has the formula $Na_2CO_3.NaHCO_3.2H_2O$. A great advantage of this salt is that it does not effloresce or deliquesce. It is readily soluble in water, and is free from insoluble matter. The writer understands that this salt has already been tried in Bradford for wool-washing with most satisfactory results. It is said to serve in the washing of flannels without shrinking them.

Messrs. Bell Brothers, Limited, Middlesbrough (No. 822), exhibit specimens illustrating the character of the salt deposits and the salt industry of the Tees: also the Schlösing ammonia-soda process. Samples illustrating the manufacture of pig iron at the Clarence Iron Works, near Middlesbrough, and also the manufacture of barium compounds, on the Tyne. For further information on Schlösing's process, see this Journal, 1885, pp. 527—528.

The Eureka Salt Manufacturing Co., Limited, Northwich, Cheshire (No. 836).—Rock salt, natural brine, and manufactured salt. A fine bust of Queen Victoria in manufactured salt forms a conspicuous object in this exhibit.

John Howarth Padgett, Brookdale Salt Works, Northwich, Cheshire (No. 826).—Various qualities and brands of salt.

R. & J. Garroway, Netherfield Chemical Works, Glasgow (No. 832).—An interesting model of the Netherfield Chemical Works, and fine specimens illustrating the sulphuric, nitric, acetic, boric, oxalic and hydrochloric acid manufactures; as also the manufacture of mordants and other dyers' and printers' chemicals.

Messrs. Peter Spence & Sons, Manchester Alum Works, Manchester (No. 829).—The leading feature of this exhibit is a colossal block of alum standing 12½ft. high, measuring 6ft. in diameter, and weighing slightly over 10 tons. This is the largest block of crystallised alum which has ever been manufactured, and has an imposing appearance, the colour being exceedingly white; the light transmitted through the mass, when looked at from the hollow inside, is of a beautiful pale blue tint.

In the case standing alongside the block there is a rich variety of manufactured products.

One pile is composed of blocks of "Turkey red" alum, manufactured by the firm. This alum is employed by all the great Turkey-red dyers, and is the purest which has ever been produced on so large a scale. Specimens of ground alum and granulated alum, and a collection of splendid alum octohedra, are exhibited.

The sulphate of ammonia is manufactured by Messrs. Spence's patented process, and is of extremely pure quality.

The column of light brown material is aluminoferric cake, an article patented by Messrs. Spence a number of years ago, and is used very extensively in sizing ordinary classes of paper, also in the clarifying of water for towns and manufactories. This article is now employed in almost every part of the world for one or other of these purposes.

"*Alfersil*" is the new sewage precipitant lately introduced by this firm, and is used for the purification by precipitation of refuse waters from manufactories and town sewage. It is claimed as the cheapest known source of soluble alumina for this purpose.

Specimens of sulphate of ammonia and sulphate of potash.

A bottle containing a liquid representing the average tint of Manchester sewage is shown. A second is a sample of Manchester sewage after purification by the *Alfersil* above referred to, the result being a very pure effluent obtained at an insignificant cost. The small bottle by the side of this contains the impurities precipitated from one gallon of this sewage. A third bottle represents the average tint of the water of the river Irwell. A fourth the same water after purification by aluminoferric. This is the quality of water with which the Ship Canal will be supplied when all the manfacturers in the district purify their refuse water. The small bottle alongside the last contains the impurities precipitated from one gallon of Irwell water.

Of the two 2ft. tubes, the first shows Manchester water as drawn from the mains of the Exhibition. The second contains the same water purified with Messrs. Spence's aluminoferric cake, used in the proportion of one ton to twenty million gallons. A comparison of these will show to what a degree of purity town's water supplies can be brought by the use of those materials. Few people have examined perfectly pure water in the analyst's 2ft. tube, and the lovely blue tint of this purified product is very striking. It may be noted that the water after treatment with aluminoferric contains no constituent which it did not contain before.

The other exhibits are sulphuric acid, manufactured from Spanish pyrites, and sulphuric acid from the spent oxide of gas works.

It is now nearly half-a-century since Messrs. Spence commenced the manufacture of alum in the neighbourhood of Manchester, and the name of the firm is now universally associated with alum and aluminous products of the best quality.

The firm also exhibits a set of the new international hydrometer devised by Mr. Frank Spence as a standard measurer both of the strength and specific gravity of solutions and other liquids, and proposed by him in replacement of the arbitrary and incommensurate hydrometric scales in use in Great Britain, the Continent and America. Mr. Spence's object is to unify the hydrometric scales of all nations. His hydrometer possesses the unique advantage of showing at a glance both the strength and specific gravity of a solution.

R. & N. Pott, 22, Southwark Bridge Road, London (No. 827).—All the vinegars exhibited are brewed from grain only. *Brown vinegars:* These are in their pure state as brewed. *Pale vinegars:* These are the same as brown vinegar, but reduced in colour by being blended with pure distilled vinegar. *Concentrated vinegars:* These are produced by an improved patented process of fractional distillation, whereby all empyreumatic and foreign flavours are expelled, leaving nothing but a pure concentrated vinegar. *Distilled vinegars:* These differ only from the concentrated vinegar in the strength, the distillation not having been carried to so high a point. Samples of grain used in the manufacture of vinegar. Samples of rape seed used as a filtering medium. Models of vat, showing the new process of acetifying patented by the exhibitors, illustrating the advantages over the old process and apparatus (of which latter there is also a model). Model of vat, showing method of cleansing and clarifying the vinegar by filtration through rape seed. Models of casks used in the trade.

In Concannon's History of Southwark mention is made of the Vinegar Works of Messrs. Pott as existing in the year 1641.

W. G. Pursell & Co., 13, Bernard Street, Leith (No. 833).—Borax in various forms suitable for manufacturing, chemical, therapeutic and domestic purposes. Refined boric acid, and a specially prepared powder for the preservation of fresh fish and other articles of food. The exhibitors refer to the statement of an Italian physician to the effect that the workpeople in borax factories appear to be safeguarded from the attacks of cholera. During the terrible epidemic of 1864—65 the workmen in seven contiguous factories in Italy were quite free from the disease, which killed one-third of the population of a village in the immediate vicinity. He recommends the internal administration of borax as a specific for cholera, in doses of five grammes per diem. He believes that it destroys not only the microbes in the intestinal canal but also in the blood.

The Trustees of the late James Buckley, 108, Higher Ardwick, Manchester (No. 834).—Crystallised ferrous sulphate (copperas), largely used, especially in black dyeing, ink manufacture, and for the reduction of the indigo vat, and other purposes.

J. M. Collett & Co., High Orchard Works, Gloucester (No. 823).—Specimens of pure bisulphites of lime, soda, potash and magnesia, and also of the sulphites of lime, potash and soda. Solutions of sulphurous acid and a sulphite composition called the "Universal Preservative." Samples of isinglass from Russia, Siberia, Hudson's Bay, Brazil, West Indies, Penang, Bombay, Kurrachee, China and Manilla.

C. B. Cullerne & Co., Crown Works, Napier Street, Liverpool (No. 824).—Samples of isinglass, finings, bisulphite of lime, sulphurous acid, etc.

Anthony K. Kaye & Son, Mold Green Chemical Works, Huddersfield (No. 828), exhibit specimens of a variety of dyestuffs, mordants, soaps, dyewoods, dyewood extracts and general drysalteries.

H. D. Pochin & Co., Limited, Quay Street, Salford (No. 835).—*Aluminous Cake.*—Mr. Pochin, previous to 1884, undertook a series of experiments for the purpose of obtaining a concentrated sulphate of alumina, which he succeeded in doing in 1854 by the decomposition of kaolin. This process was patented in 1855. The quantity consumed in the first year was only a few hundred tons, but before the patent expired the sale had increased to very many thousands of tons per annum of his own manufacture, besides a quantity made by other persons under a royalty paid to him. This article (aluminous cake) is very largely used by paper makers.

Sulphate of Alumina is produced from aluminous cake, this being much cheaper than by employing the old process, which consisted in precipitating the iron from the very crude sulphate of alumina by means of ferrocyanide of potassium, This article is used in the manufacture of tissue papers and the finest kinds of writing papers.

Concentrated Alum.—A neutral sulphate of alumina of a low price, which may be advantageously employed for paper sizing and the precipitation of waters containing sewage and other flocculent matter. This article contains 14 per cent. of alumina, and will compare favourably with any alumina compound now in the market at an equal price. The results are not equal to those obtained by the use of aluminous cake, but they are satisfactory to those who prefer a neutral sulphate.

It is perhaps desirable to explain here that all paper would be blotting paper unless it was made partially waterproof by precipitating with the pulp in the process of manufacture, rosin obtained from a rosin soap, and then mixing with either aluminous cake or sulphate of alumina—the waterproofing material consisting, in the aluminous cake, of hydrated silica, alumina, and rosin; and in the case of sulphate of alumina, of rosin and alumina alone.

China Clay.—This article, which is the raw material for the aluminous cake and sulphate of alumina, is found in very large quantities in Cornwall, and results from the decomposition of felspar in granite. It is in its natural condition, pipe clay, but as made artificially is a very pure silicate of alumina. Messrs. Pochin are amongst the largest manufacturers in Cornwall, the production and sale amounting to tens of thousands of tons per annum. It is also used in pottery, and is one of the best articles used for stiffening and finishing cloth.

Binarseniate of Soda as used by calico printers as a dung substitute.

Dextrin has been made by this firm since the year 1830.

Acetate of Alumina obtained by a new process, which has been in operation for the past two and a half years. It is free from colour and from excess of acid.

The *Refined Rosin* exhibited is the result of the patent taken out by Messrs. Hunt and Pochin. By this patent common black rosin is distilled by superheated steam and deprived completely of its colouring matter.

Patent Anhydrous Rosin Size.—This size is prepared for use with Pochin's patent aluminous cake, and is quite free from water. When used in the following proportions, the greatest economical results are obtained—there is no loss of size on the one hand, or aluminous cake on the other. This result, we think, has in very few cases been obtained by paper-makers, previous to the introduction of this size: it is now obtained with certainty, if used in the following proportions: To 5lb. of the size, 7lb. of aluminous cake. The best way of proceeding is to dissolve the size in water, in the proportion of say 3lb. to one gallon of water, boil it for about 15 or 20 minutes, *so as to ensure complete solution*: it is then fit for use.

In the Irish Section, Messrs. Harrington Brothers, of the Shandon Chemical Works, Cork, exhibit a variety of preparations comprising oxides for the glass, porcelain and enamel industries, such as cobalt, nickel, copper, tin and other oxides. Besides these are metallic tungsten and its salts, stannate of soda, oxalate of antimony, penta- and trichlorides of phosphorus, golden sulphide of antimony, etc. A series of organic preparations is also shown, as well as one of chemically-pure salts for analytical and scientific purposes, and finally a set of pharmaceutical preparations. This enterprising firm publishes an exceedingly neat price list in the form of a small book, which excels even those supplied by well known firms in Germany. This serves not only as a price list, but as a pocket-book, since it contains most of the usual tables, such as those of the atomic weights, specific gravities, and percentage strengths of acids and alkalis, alcohol tables, with other useful data.

The meetings of the London Section will be held on the first Monday in each month.

SESSION 1887–88.

Prospective Arrangements.

Dec. 5.—Professor Dewar, M.A., F.R.S. (President of the Society), "The New Weldon-Pechiney Process for the Manufacture of Chlorine from Chloride of Magnesium."

Communications to be addressed to the Local Secretary.

Mr. C. C. Hutchinson, of Stratford, desires to state that he was not the member of that surname present at the meeting of the London Section of the Society, held November 7, 1887.

Meeting held Monday, November 7, 1887.

MR. D. HOWARD IN THE CHAIR.

NOTE ON THE COMPARATIVE ANTISEPTIC VALUES OF CHLORIDES, NITRATES AND SULPHATES.

BY C. T. KINGZETT, F.I.C., F.C.S.

The simple observations of which I propose in this note to give a brief description, were not intended to serve as a definite measure of the antiseptic values of the substances employed, but were only made by way of a preliminary introduction to another study. As, however, they were comparative in character, they may possess some little interest and value. Two series of experiments were made, one being upon flour-paste, to ascertain for what period certain quantities of 5 per cent. solutions of the various substances protected it from the growth of mould, and the other upon extract of beef, to ascertain for what period the same 5 per cent. solutions protected it from putrefaction.

It is to be noted that in cases where the salts were not perfectly soluble in water, the solutions containing the undissolved compound in suspension were used.

The manner of proceeding with the flour-paste observations was as follows: In each case 4grms. of flour were boiled up with the water until a gelatinous product was obtained, and when nearly cold the solutions to be tested were well stirred in. One series of observations (*a*) was made with a mixture of 4grms. flour, 38cc. water, and 2cc. of the 5 per cent. antiseptic solutions; and another (*b*) with 4grms. flour, 36cc. water, and 4cc. of the 5 per cent. antiseptic solutions. Practically, therefore, the mixtures contained respectively about 5 per cent. and 10 per cent. of the 5 per cent. solutions under examination. In other words, the actual weights of substances employed in these two series of trials were severally 0·1 and 0·2grm.

By way of comparison, an unprotected mixture of flour and water was similarly made and employed, using 4grms. flour and 40cc. water.

For the other series of observations (*c*) 5lbs. of lean fresh beef was digested at 40° C. with distilled water during three hours, the extract was diluted up to 4 litres, and after cooling, strained through fine muslin.

Quantities, each of 95cc., of this extract were then taken, and to them was added 5cc. of the respective 5 per cent. solutions under examination (= to 0·25grm. dry substance). All the test glasses were left uncovered.

SUMMARY OF RESULTS.—SERIES A.

CHLORIDES.

On 2nd day mould was seen upon the following mixtures:—$NaCl$, $CaCl_2$ and $SrCl_2$.*

On 3rd day on NH_4Cl, $BaCl_2$, $MgCl_2$, $ZnCl_2$.

On 4th day on the standard flour-paste.

On 5th day on $SnCl_2$.

On 6th day on Al_2Cl_6.

On 9th day on Fe_2Cl_6.

On 16th day on $PbCl_2$.

On 26th day the following mixtures were still free from mould, but had dried up:—$HgCl_2$ and $CuCl_2$.

NITRATES.

On 4th day KNO_3, $NaNO_3$, NH_4NO_3, $Sr(NO_3)_2$, $Ca(NO_3)_2$, $Mg(NO_3)_2$.

On 5th day flour paste standard, $Ba(NO_3)_2$, $Zn(NO_3)_2$ and $Fe(NO_3)_2$.

On 7th day $Pb(NO_3)_2$.

On 15th day $Hg_2(NO_3)_2$ (mercurous nitrate).

On 24th day the $Cu(NO_3)_2$ mixture had dried up free from mould.

SULPHATES.

On 5th day mould was to be seen on the following mixtures:—flour-paste standard, K_2SO_4, Na_2SO_4, $(NH_4)_2SO_4$, $Al_2(SO_4)_3$, $MnSO_4$, $ZnSO_4$.

On 7th day on $MgSO_4$.

On 9th day on $FeSO_4$.

On 20th day on $CuSO_4$.

On 24th day the $HgSO_4$ mixture had dried up free from mould.

SUMMARY OF RESULTS.—SERIES B.

CHLORIDES.

On 2nd day mould had appeared on the $CaCl_2$ mixture.

On 3rd day on KCl, $NaCl$, NH_4Cl, $BaCl_2$, $SrCl_2$.

On 4th day on flour-paste standard, $MgCl_2$, $ZnCl_2$.

On 7th day on Al_2Cl_6.

On 9th day on Fe_2Cl_6, $SnCl_2$.

On 26th day the following mixtures had dried up free from mould:—$HgCl_2$, $PbCl_2$, $CuCl_2$.

NITRATES.

On 4th day KNO_3, $NaNO_3$, $Sr(NO_3)_2$, $Ca(NO_3)_2$.

On 5th day flour-paste standard, NH_4NO_3, $Ba(NO_3)_2$, $Mg(NO_3)_2$, $Zn(NO_3)_2$.

On 7th day $Fe(NO_3)_2$.

On 8th day $Pb(NO_3)_2$.

On 20th day $Hg(NO_3)_2$.

On 24th day the $Cu(NO_3)_2$ had dried up free from mould.

SULPHATES.

On 5th day on the flour-paste standard, K_2SO_4, Na_2SO_4, $(NH_4)_2SO_4$, $Al_2(SO_4)_3$, $ZnSO_4$.

On 7th day $FeSO_4$, $MnSO_4$.

On 9th day $MgSO_4$.

On 24th day $CuSO_4$ and $HgSO_4$ mixtures had dried up free from mould.

It should be mentioned that, although in the preceding records, the first day on which mould made its appearance on the pastes has been noted in each case, yet the quantity so appearing differed within wide limits; in some instances the growth was barely decisive in character, whereas in others it was well developed.

Reviewing the results generally, it may be said that the compounds of the alkalis and alkaline earths appeared in many instances to promote the growth of mould in the same sort of way as Warrington has observed the presence of gypsum facilitates the nitrification of urine. In no instance was the growth of mould postponed by the presence of salts of potassium, sodium or ammonium, and among the compounds of the alkaline earths, magnesium sulphate alone exhibited a slight prohibitive effect. The zinc compounds rank with those of the alkaline earths. The sulphate of manganese in the higher proportion slightly delayed the growth of mould. The compounds of iron, tin, lead and aluminium exercised distinct but not very powerful prohibitive effect, excepting the chloride of lead, the antiseptic action of which must be described as incisive and as ranking with the sulphate of copper. As to copper and mercury, the chlorides of those metals rank apparently as of highest and equal value, side by side with nitrate of copper and sulphate

---

* The KCl paste did not go mouldy, but smelled sour o the 7th day, when maggots appeared.

of mercury. Somewhat below these compounds in antiseptic action stands sulphate of copper and nitrate of mercury, the first-named of these substances being decidedly the most effective of the two.

SUMMARY OF RESULTS.—SERIES C.

Chlorides.

On the 2nd day the solutions containing the following salts were putrid:—KCl, NaCl, NH_4Cl, $BaCl_2$, $SrCl_2$, $CaCl_2$, $MgCl_2$. (Mould on $BaCl_2$ solution 3rd day).

On the 6th day Al_2Cl_6, Fe_2Cl_6, $PbCl_2$, $SnCl_2$. (Mould on Al_2Cl_6, $PbCl_2$ and $SnCl_2$ solutions on 3rd day).

On the 8th day, $ZnCl_2$.

The solutions containing $CuCl_2$ and $HgCl_2$ alone remained good during the whole period of observation (summer weather)—viz., some 10 days.

Nitrates.

On the 2nd day the following solutions were putrid:—KNO_3, $NaNO_3$, NH_4NO_3, $Mg(NO_3)_2$, $Fe(NO_3)_2$.

On the 3rd day $Sr(NO_3)_2$, $Ca(NO_3)_2$ (also mould).

On the 6th day $Ba(NO_3)_2$, $Pb(NO_3)_2$ (mould appeared 3rd day).

On the 10th day $Zn(NO_3)_2$ (been suspicious some three days).

The $Cu(NO_3)_2$ and $Hg(NO_3)_2$ solutions alone remained intact from putrefaction, although there was a speck of mould on the copper solution on the 5th day; it did not grow appreciably.

Sulphates.

On the 2nd day the following solutions had broken down:—K_2SO_4, Na_2SO_4, $(NH_4)_2SO_4$, $MgSO_4$, $MnSO_4$.

On the 3rd day $FeSO_4$.

On the 6th day $Al_2(SO_4)_3$, $ZnSO_4$ (also mould on both).

The $CuSO_4$ and $HgSO_4$ solutions alone stood the test, but a speck of mould appeared on the copper solution on the 4th day; it did not appreciably develop.

The standard meat extract was very bad on the 2nd day.

With respect to the observations made with extract of meat, the results generally accord with those of the flour-paste series, excepting that the salts of zinc appeared to exercise a distinctly superior antiseptic action to that which they exhibited in protecting flour paste from the growth of mould. The chloride of lead did not behave up to expectation, based upon the flour-paste experiments with that substance, but in all probability its effect is modified by the precipitation which the solution undergoes when added to meat extract. The compounds of mercury and copper again come out as most effective, and, if any choice is to be made, it seems to fall upon the chlorides of those metals.

DISCUSSION.

The **Chairman** said the thanks of the meeting were due to Mr. Kingzett for his record of an admirable and accurate research, the value of which he had underestimated. It was only by experiments of this kind, made with various substances and under varying conditions, that one could realise the great differences in the action of various reagents on various micro-organisms. Without such knowledge there was the danger of over-wide generalisation from insufficient evidence. For example, the action of boracic acid was widely different on animal and on vegetable life. To animal life it was a doubtful poison, but to vegetable life it was most deadly. The whole question of the application of such bodies to preservative or disinfectant uses, therefore, depended on the nature of the substances to be treated. Mr. Kingzett's experiments were very interesting as showing that it was only in very dilute solutions that one could determine the specific action of the antiseptic body. Everybody knew that a strong solution of common salt was a powerful preservative, and it was desirable that it should be equally well known that the same body, if dilution were carried beyond a certain point, not only ceased to be a preservative agent, but probably encouraged the growth of organisms. Mr. Kingzett's experiments seemed to show that the most powerful destroyers of these low forms of life were the salts of mercury and copper. Without wishing to propose that blue vitriol should be run into the drains, he certainly thought that this salt ought to have a more extended use for sanitary purposes, as it was comparatively inexpensive, and its action was far more powerful than was generally realised.

Mr. **Tyrer** considered the paper to be a striking example of the good work which many members might, but from motives of diffidence did not, bring before the Society. It would be most useful if results of this kind—*i.e.*, laboratory notes—were recorded in the Society's Journal, with the discussions to which practical points always gave rise.

Mr. A. H. **Hutchinson** expressed surprise that Mr. Kingzett had not compared the action of the bodies dealt with in his paper with that of other preservative agents. He would be glad if Mr. Kingzett would explain the nature of the action of his Sanitas solution, and state why it prevented decomposition where bichloride of mercury did not.

Mr. J. **Heron** wished to ask what was Mr. Kingzett's object in making these experiments? It seemed to him that the object was to determine at what period mould would first appear. Nothing had been said about other forms of micro-organisms, which could be seen only under the microscope. It was well known, however, that where mould might appear on the surface of the bodies treated, other organisms originally present might have been destroyed by the antiseptic used—in short, that the salts would have a different antiseptic action on different forms of organisms. He would like to know whether Mr. Kingzett had differentiated his experiments, whether he could say, for instance, that nitrate of zinc would destroy bacteria and other ferments, as well as mould, up to a certain point, or that mercury chloride would practically kill everything it came in contact with, or, at least, prevent its development. He understood that Mr. Kingzett had boiled the flour and the meat extract. It would have been much better, however, to have simply mixed the substances with water and then added the antiseptics.

Mr. **Kingzett**, replying to the last speaker's remarks first, pointed out that in describing how his experiments had been conducted, he had expressly stated that the flour paste had in all cases been prepared by boiling the starch with water only, and that when the paste was nearly cold the antiseptic solution was stirred in, and the mixture placed in open glasses exposed to the air. In the case of the meat extract, to have boiled it would have been to entirely defeat the experiment, because it would have coagulated. He had avoided that by preparing it at a temperature at which the constituent albumen would not coagulate. The experiments were only intended to ascertain the comparative antiseptic value of the various solutions employed upon the specific growth of mould, and the active bacteria—notably *bacterium termo*—concerned in the process of putrefaction, and for these two growths there was no question of the value of the comparative results obtained. He willingly admitted that if he wished to place before a scientific body an adequate explanation of the action of any one antiseptic, he should not deal with a mixture like flour paste, nor with extract of beef. He would prefer to take a number of well-known simple substances. For example, he would take so much sugar, and ascertain how much alcohol and carbonic anhydride were produced, and in every case would not be content till the sum total of the products equalled the amount of substances operated on. That had not been his object in the present experiments, which were merely preliminary to such a study. Some two years ago he had occupied himself for eight months with an investigation of that kind. In that case the antiseptic employed was exclusively his own "Sanitas" fluid. He had always regretted that he did not communicate those results to the Society, because they were quantitative throughout. Even if resuscitated now they would be robbed of much of their interest, because they had been already published in pamphlet form. With reference to Mr. Hutchinson's remarks, he could only say that he had studiously avoided any reference to his own products. If he had desired to compare the "Sanitas" products with other antiseptics, he would have been compelled to pursue the investigation much further than seemed desirable on the present occasion. Thus, instead of being content with the bare comparative antiseptic results as obtained from laboratory experiments, he would consider it necessary to ascertain how far it was possible to take practical advantage of them not only in a public sense, but in such special direction, also, as in the practice of antiseptic surgery, and the chemical modification (destruction) of those poisonous substances which are often produced as concomitants of the life and development of micro-organisms.

DISCUSSION ON MR. J. RUFFLE'S PAPER ON "THE CORRECT ANALYSIS OF SUPER PHOSPHATES, PLAIN AND AMMONIATED"

—Printed in the July (1887) Number of the Society's Journal.

Mr. B. E. R. Newlands, while fully recognising the great merit of Mr. Ruffle's work, could not agree with his views on certain points. He thought that Mr. Ruffle attached too much importance to the quantity of water in these manures. His process would give the percentage of uncombined water; but then that percentage would vary week by week as the manure aged, and so it would be impossible to verify results. On the other hand, by the old method of determining the whole of this useless water at 212°, one got uniform results. Supposing a manure intended for export to America; a certain degree of moisture guaranteed; and that moisture determined by the calcium chloride test at 10 per cent. On its arrival in America, some weeks later, the results would appear so much lower that the American buyer would be apt to lose faith in the skill of the London analyst. Mr. Ruffle was of opinion, too, that there was practically no monocalcic phosphate, on the ground that "the SO_3 is present in less quantity than is necessary to combine with all the CaO." It seemed to him, however, that, there being insufficient SO_3 to combine with the three molecules of lime, this was a good reason for its combining with two—on the principle that an army of soldiers desiring to take three cities, but being insufficient in numbers, would make sure of two cities first rather than attempt the impossible feat of taking all three. Mr. Ruffle's paper was an interesting one, and abounded in conscientious work; he hoped it would do much to ventilate an important subject and to clear up results which had been, to some extent, a disgrace to public chemists, because of their variations and incongruities.

Mr. Bernard Dyer thought he might anticipate Mr. Ruffle's reply to Mr. Newlands in so far as to say that if, continuing the military comparison, "third regiment of molecules" were read for "third molecules," the passage would be perfectly clear. The paper had finally disposed of the supposition that the so-called monobasic phosphate formed a constant or sometimes even a very appreciable quantity of the so-called "soluble phosphates" present. In devising his method of moisture determination, and in the work that had led up to it, Mr. Ruffle had done a great deal for the chemistry of the subject. There would, of course, be practical difficulties in the way of adopting the process, the chief one being perhaps that of getting chemists to agree on this mode of statement. Each one would be afraid to take a new departure, for fear of bringing about what would be looked upon as hopeless clashing. With regard to Mr Ruffle's general method of stating results, the old method of writing out an analysis of superphosphates could be defended on only one ground: that it was convenient because it was conventional. Scientifically, it was lamentable that four out of five items of an analysis should be more or less meaningless; but, practically, it was of little consequence. The cases in which full analyses of superphosphates were required were rare, the usual course being merely to show the percentage of soluble and insoluble phosphates of ammonia, and sometimes of (so-called) moisture. But, on the scientific question, he must quarrel with the author, not for introducing a reform, but for not being a good thorough-going Radical while he was about it. In this case Mr. Ruffle, if he would forgive him for saying so, was posing rather as a sort of analytical Whig. He (Mr. Dyer) objected to analyses which mixed up acids and bases stated as such with salts stated as such. Mr. Ruffle had quarrelled with the old method because of its "assumptions," but it was surely an assumption on his part to make the insoluble phosphoric acid all tribasic phosphate of lime, whereas a considerable percentage of it might be phosphate of iron or of alumina. He had also assumed that all the SO_3 was present as sulphate of lime. But there were many bases present: oxide of iron, alumina, magnesia, potash and soda. Why then give all the SO_3 to lime? Then, too, the difference that Mr. Ruffle had shown in the composition of ordinary superphosphate and ammoniated superphosphate came in to bother one, the total sulphuric acid in the one case being calculated as sulphate of lime and in the other case the lime, other than insoluble phosphate, being stated as sulphate of lime. In the one case, he assumed the "sulphate of lime" from the SO_3; in the other case from the lime. But there were different degrees of "ammoniation," so to speak, and the variation in composition might be considerable in different cases. He would suggest that, to place the thing on a scientific basis, no assumptions at all should be made, but that the various constituents should be stated as they were determined—acids and bases being written separately. He felt, as would all brother agricultural analysts, personally grateful to the author for the work he had done, but while having a full sense of the value of that work, he would like to see the reform in the statement of results—if there were to be any reform—made complete.

Mr. T. W. B. Mumford, referring to Mr. Newlands' remarks that water had no value, said that a manufacturer who produced a superphosphate containing much water soon found that he had to put his hand in his pocket and allow for it. Mr. Ruffle's experiments had shown that it was possible to determine the amount of actual or uncombined moisture, whereas the old method determined the whole of the water present. Assuming that a superphosphate tested by the old method gave 20 per cent. of moisture, by the calcium chloride test it might show, say 10 per cent., which later on would be somewhat reduced, as more of the water would combine with sulphate of lime. But if the same manure were then again tested by the water-bath, it would still show 20 per cent. of water; and hence the manufacturer was placed in an invidious position. It was therefore very desirable that analysts should adopt some one method which could be depended on.

Mr. G. D. Macindoe said that was just the point at issue. All who understood the American trade knew that if the calcium chloride method were adopted makers would be required to guarantee a certain moisture *on arrival* in America. Sellers had to guarantee a 14 per cent. moisture, and if they were to be called on to adopt what it might be, say after three months, more difficulties and quarrels would arise than at present.

Mr. A. H. Hutchinson differed from both the author and Mr. Dyer as to the form in which the results of the analyses should be expressed, and indicated on the black board the formulæ which he considered should be used.

Mr. Hughes pointed out that the difficulties which arose between manufacturers of superphosphates and American buyers practically turned upon the question of what *was* moisture. If manufacturers would agree to adopt either the determination by the calcium chloride method or by the water-bath method, and stipulate for a certain percentage by one or the other method when contracts were made, many of the disputes which now occurred would be avoided. It was matter for regret that the subject of the statement of analytical results in regard to superphosphates should not have been taken up long before; and Mr. Ruffle deserved their thanks for his work. He would like some further information with respect to the free acid in superphosphates. He had found that when an excess of sulphuric acid was used there was a perceptible amount of free acid, and if the superphosphate were kept for some time it became wet, not dry. In such cases the determination of the free acid would be of great use to the manufacturer.

Mr. Crowder thought that Mr. Hughes had answered his own question. If a superphosphate contained free acid, it was clear that it was badly made and that too much acid had been used. His objection to analyses as at present expressed, was that statements were made which sellers found it very difficult to prove, and Mr. Ruffle had done good service in drawing attention to the subject. The whole of the phosphoric acid was calculated as monocalcic phosphate, whereas really two-thirds only was so. Mr. Ruffle had, however, been illogical in not stating his insoluble as well as his soluble phosphate in terms of phosphoric acid, so that anyone could readily see what it represented in phosphate of lime. The question of moisture could be regarded from two points of view, the commercial and the scientific standpoints. The commercial manager of course regarded it from the first, and the works manager from the other standpoint. It might be necessary to make elaborate analyses for the works manager, but for the other it was waste of time. The question of moisture did not often arise in the English trade. The condition of the manure was the main point. One might have half-a-dozen different manures all in good, dry, powdery condition, and yet showing several per cents. difference as to moisture. Therefore moisture did not represent the condition, and it was the latter point to which the farmer chiefly looked. Mr. Ruffle's plan for the determination of moisture had doubtless great scientific value, but was not of much commercial importance. Mr. Ruffle argued rightly enough that if a thing was "worth doing at all it was worth doing well." Still that mode of analysis entailed great expenditure of time. If an analysis was required during the day, and it took one-and-a-half days to do it by the $CaCl_2$ method, surely it was better to use the old water-bath method and so get the work done quickly.

Mr. C. G. Cresswell said that users of these manures complained greatly of the method in which analyses were stated to them. Farmers of average intelligence found themselves unable to grasp the information given to them, though anxious to do so, simply because the terms employed were as so much Greek to them. It was to be desired that such useful works as Mr. Wyatt's "Modern High Farming" should become generally known to farmers, since they would therein find a clear and simple translation of all the analyses with which they were concerned.

The Chairman, in calling on Mr. Ruffle to reply, said that he would probably tell them that he had stated his phosphate as "soluble" and "insoluble," because those were the states in which it was found in the manure. He must nevertheless admit that even to the mind of the average chemist there would be an advantage in stating both in terms of phosphoric acid.

Mr. Ruffle, in reply to Mr. Newlands, admitted that the results of his method would vary with time: but it was right that they should do so, since the composition of the manure itself varied with lapse of time. That seemed to him an argument in favour of the adoption of the proposed method. He thanked Mr. Dyer for his suggestion of the "regiments" of molecules of sulphuric acid attacking the equivalents of lime, which was quite in accordance with what he wished to express. It had been suggested that the sulphate of lime should be determined by one method for both plain and ammoniated phosphates. He thought not. If one method were adopted the results would be incorrect, for there was an essential difference between the two compounds. In the one case the lime could be estimated from the sulphuric acid, in the other it could not. The first duty of the analyst was to get the result correct in each case, although it might entail more trouble.

Mr. Newlands asked whether the sulphate of lime could not be determined from the lime in each case?

Mr. Ruffle replied that it could not, for whilst possible in ammoniated superphosphates, owing to their containing practically no lime as monocalcic phosphate, yet in plain superphosphates the amount of lime present as monocalcic being appreciable, was yet too irregular to permit any rule. As to the question of whether the water in these manures was of any value, it was to be remembered that although the manure was not sold at so much per unit of water, yet if it were the fact that a maker had a manure which was wet and out of condition, and by keeping it for two or three months it came into good condition, simply by the water combining, the water question did appear to be of considerable importance. He did not believe that American buyers would succeed in forcing any manufacturer to guarantee a certain condition on arrival. No maker would agree to that, not knowing the time which would be taken in transit. The most he would agree to would be to deliver it on this side in a certain condition and have it examined here. Mr Dyer had complained that he had mixed up acids, bases, and salts. That was perfectly true. He had done so because it was the practice among merchants and brokers to speak of soluble P_2O_5, and he thought it would be going too far to introduce such terms as soluble phosphoric acid hydrated, or soluble phosphoric anhydride. He had carried the matter as far as it was likely to be accepted commercially. Whether the insoluble phosphoric acid existed as insoluble phosphate of lime, alumina, or iron, the usual course was, after showing how much soluble phosphoric acid could be got out, to call the remainder insoluble phosphate. He would have liked to state his results with more scientific accuracy, but feared to go too far lest his readers would not accompany him. He could only claim to have started the subject. No doubt as time went on other questions would arise in connection with it, and if he could make a further communication he would willingly do so.

DR. J. CAMPBELL BROWN PRESIDING.

CHAIRMAN'S OPENING REMARKS.

Dr. Campbell Brown opened the Session with the following short address :—

I shall probably be not far wrong if I assume that the great majority of manufacturers think mainly of their manufactures as a means of making money. Yet manufacture performs far higher functions, which should not be lost sight of, but which should be a source of pride to the established, and a consideration to the prospective, manufacturer. He, by his industry, benefits not only himself, but the rest of the world, providing employment for those under him, and generally a useful product for his customers. He has the opportunity of choosing whether he will devote himself to the supply of something beneficial to his fellows, or something which will merely tickle their fancy or please their senses. He has the opportunity of meeting with new facts and new things which may add to the general store of knowledge ; these he ought not to neglect, but either follow them up himself or take care that some one else has the opportunity of doing so ; and he ought to impart his knowledge to others, unless in such instances where it is necessary to withhold information for a little time in order to secure commercial success. He often has the opportunity of fostering in many ways the growth of the science, and of perfecting the art of chemistry, by working out details or making suggestions whereby others may do so.

The most satisfactory thing to contemplate in looking at the history of the development of the akali manufacture, for instance, is not that it made the fortunes of the fathers and grandfathers of so many members of this Society, nor even that it gave employment to so many thousands of workmen, although both were great things to accomplish ; but that it brought cheap and abundant means of cleansing themselves and their dwellings and raiment within the reach of every family among the civilised nations of the earth, and facilitated in countless ways the manufacture, not only of soap, but also of many other things of high utility, which would never have been introduced to the public use without a plentiful and economical supply of sulphuric acid, alkali or chlorine.

One of the greatest developments that we have witnessed has been that of the coal-tar industry and its numerous dependencies. When one sees the glaring colours which are now flaunted before the public eye, often without any thought of harmony and with no consideration of appropriateness of position or surroundings—in advertising placards, house decoration, dress and so forth—one is sometimes tempted to ask whether the production of these new dyes has been a good thing for mankind, and whether, when our last mines are worked out and coal-tar dyes cease to be manufactured, the world will be any better for having had them, and whether the huge industry, which is at present flourishing, is not a waste of time, and of carbon compounds that would be better saved to keep us warm in winter—whether, at least, its highest merit is not that it affords a present means of livelihood to so many thousand workmen.

We sometimes hear it said that the production of artificial alizarin has done an immense service in setting free so many square miles of land for the growth of grain ; but I am afraid this is not a great merit, and that perhaps the Egyptian farmer might have been better off with his madder crop than with his grain crop. The world has abundance and superabundance of acres on which to grow food. The great difficulty seems to be not to find acres to grow food on, but to find something that will grow on all the acres that are in cultivation or available for cultivation, and that will sell at a price which will enable the grower to buy something more than the mere grain necessary to keep him alive.

It is possible that the art sense may be influenced by some of the colours which have been introduced and popularised by the coal-tar industry ; but no improvement of that kind, if it takes place at all, can last after the supply of material has ceased.

When all the available coal in the world has been exhausted, and we have to depend again on tar from vegetable sources, and when our fuel has to be cut from living forests instead of dead mineralised ones, and the progress of manufacture of coal-tar colours has shrunk to insignificant dimensions, the world will still have a knowledge of the structure of chemical compounds, and of the modes of transformation which they undergo—knowledge which has been acquired through the stimulus given to organic research by this industry, and whose acquisition would not have been possible but for the industrial development of coal-tar products.

The knowledge which we already have of the laws and modes of organic synthesis, of the symmetry which we see in the groups of carbon compounds from the simplest to the most complete—knowledge which is increasing every day, and is destined to increase for a long time to come—is the real justification of that waste of our sources of crude carbon compounds out of which it has sprung, the highest reward for all the ingenuity, labour and resources which have been expended upon the coal-tar industry, and will be the most lasting benefit which that industry has indirectly bestowed on mankind. This, rather than cheap alizarin, gaudy bills, brilliant shop windows and rainbow-coloured dress, is the thing of which the coal-tar manufacturer should be proud.

Casciorolus doubtless made excellent shoes and sold them at a fair price ; but the world would not know his name nor feel the least indebted to him, had he not introduced into the chemical laboratories of his time barium sulphide or Bononian phosphorus.

John Kunkel was manager of a Potsdam glass manufactory which produced a famous ruby glass ; he also published a book in which all the known receipts for making glass are given. Yet, when one names Kunkel, it is phosphorus and not glass that rises before one's mental vision.

Balard is revered now not because he manufactured and sold so many thousand kilos. per week of salt extracted from sea water; but because he one day, in the course of his experiments with the mother-liquor, observed some reddish-brown vapours which he had never seen nor heard of before, and did not carelessly neglect them, nor selfishly conceal his discovery, but made a very elaborate examination of these red fumes and made known to the world the now very useful element—bromine.

Joule doubtless made excellent beer, because he is the sort of man who does everything well that he undertakes; but his great work for which the world is most indebted to him, and by which he will be remembered with gratitude throughout all time, was his determination of the mechanical equivalent of heat, whereby he laid the foundation of chemical dynamics and of the science of thermal chemistry, as well as brought about a revolution in an important branch of physics

It is desirable that the manufacturer should remember that he has other and higher privileges, and that nobler duties devolve upon him than those which necessarily occupy the greater part of his thoughts during business hours.

◆◆◆

COMPARATIVE EFFICIENCY OF VARIOUS MODES OF TREATING LIQUIDS WITH GASES.

BY FERD. HURTER, PH.D.

Two years ago I read a paper before this Section, entitled "Comparative Efficiency of Various Modes of Treating Liquids with Gases." The following short paper forms a continuation. I can hardly expect the members to recollect that paper, and I will, therefore, recapitulate briefly its contents. The intention of the paper was to compare the efficiency of various apparatus for bringing into intimate contact liquids and gases, that apparatus being considered most efficient, which produces the most intimate contact with least expenditure of mechanical work. I divided the various modes of treating a liquid with a gas into three classes. The first method consisted in propelling the gas divided into small bubbles through a column of liquid. The second method, the inverse, divides the liquid into fine drops, which fall through a column of gas, and in the third method, which is the most important, the liquid is spread over extensive surfaces of solids, the gas filling the interstices between the solids.

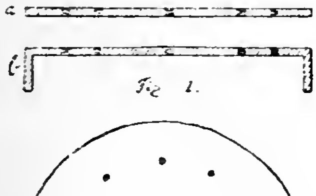

Fig. 1.

In my last paper I only dealt with the mechanical principles of apparatus of the first class, and showed that it is cheaper to force the gas through the liquid than to pull it through, and that it is best to allow the gas to escape at atmospheric pressure from the surface of the liquid, when that is possible. The arguments were based upon experiments on the behaviour of gas bubbles under various pressures, and upon the uniform velocity with which they rise through the solution. I assumed a uniform and perfect distribution at the bottom of the column of liquid in all cases, and I gave a warning that the mere consideration of mechanical principles and disregard of the chemical side of the question might lead to the reverse of economy.

It is my intention to-night to complete my remarks as to how to obtain a good distribution of the gas; and also to show how the chemical side of the question may influence the economy of the process.

The usual methods of distributing a gas at the bottom of a column of liquid are:—Either the employment of a false bottom (Fig. 1), which is a perforated plate sometimes plain (*a*), sometimes provided with a downward flange so as to make it into an inverted perforated flat dish (*b*), or the distributor consists of a system of radiating pipes, perforated with small holes (Fig. 2), or it often consists of a bell or cone open at the bottom (Fig. 3), under which the gas is delivered, and from the serrated circumference of which the gas rises in a number of fine streams.

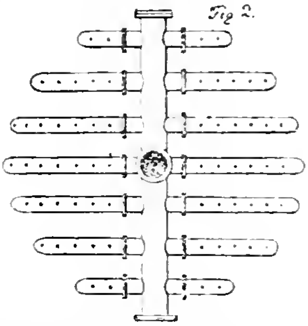

Fig. 2.

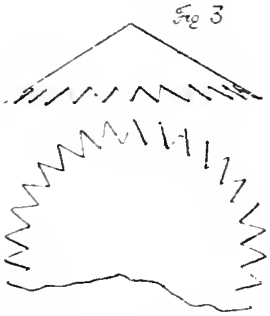

Fig. 3

Only the false bottom and the pipe system can be called distributors in the wider sense of the word, since they alone can distribute a gas equally over a large area, whilst the serrated cone only causes the gas to rise in a number of streams instead of only one, and is a distribution in that sense, but it does not attempt to distribute the gas equally over a large area.

The purpose of the perforated plate and the perforated pipes is to divide the gas into as many streams as there are perforations, and to equally distribute these streams over the sectional area of the vessel.

A rule often observed by engineers in designing these distributors, is to choose the number and size of the perforations so that the total area of the perforations shall be at least equal to or rather larger than the area of the supply pipe.

I had some doubts as to this rule, and I decided to test the question as to whether the gas would always divide itself into as many streams as there are perforations by direct experiment.

At the bottom of a circular glass vessel I placed a flanged perforated plate, as shown in Fig. 4. At the side of this false bottom through the flange, I provided an inlet pipe. Another inlet pipe passed through the bottom of the glass vessel in the centre. I may at once state that in all experiments it was found perfectly indifferent which of these two inlets was used, the position of the inlet pipe in no way affected the result.

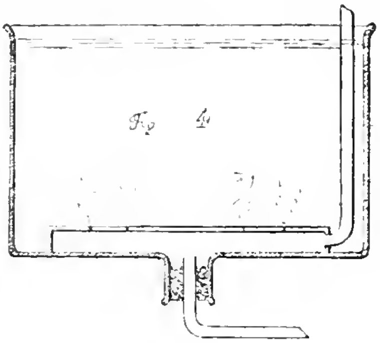

Fig. 4

The false bottom had two circular rows of holes, one larger circle containing 12 holes, and a smaller circle containing six holes, all of exactly the same diameter, $\frac{1}{16}$ of an inch. The supply pipe was $\frac{1}{4}$-in., and it will be seen that 16 holes would have equalled the supply pipe.

On admitting air into this arrangement it was found that only a particular amount of air could be fairly distributed with it. When a small quantity of air was used, only a few of the perforations were supplied; no gas issued from the others. Spasmodically the holes which were supplied would cease to deliver and others would start. By increasing the quantity of air a greater number of the holes began to deliver, and with a certain supply all the 18 holes were fairly and regularly supplied. But if now the quantity of air was still further increased, it would find its way in large masses from under the flange of the false bottom, and regular distribution no longer existed.

I measured the quantity of air which each hole delivered; first when only a few of the holes were supplied, and secondly when the whole 18 were all fairly supplied. I measured it by allowing it to enter a vessel held over the hole, and observing the time required to completely fill that vessel (see Fig. 7).

I thus found, first, that every one of the 18 holes delivered the same amount of air, and secondly that when only a few holes were working, the amount of air delivered by one of them was the same as when the 18 were working. It was evident, therefore, that the relative areas of the perforations and the supply pipe had no connection whatever with the regular distribution, but that the number and areas of the perforations must depend upon the quantity of gas to be distributed, and that only one particular quantity of gas could be distributed by a given distributor of this type.

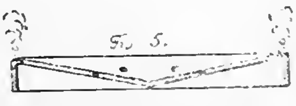

Fig. 5.

I next tried another form of false bottom, as shown by Fig. 5. This was intended to deliver and distribute two different quantities of gas. The distributor consisted of an indented flat cone; apex downwards, and a downward flange at the periphery. Twelve holes were drilled into the ridge, and six on a circular line on the side of the cone. The gas could be delivered either from the supply pipe soldered to the flange, or from the central pipe through the bottom of the glass vessel. The results again in no way depended upon the position of the inlet pipe.

The intention was, that a small amount of air should issue only from the holes in the ridge, and a larger quantity of air should supply both the holes in the ridge and the holes in the side of the cone.

On delivering a small quantity of air any number of holes up to the 12 in the ridge could be gradually supplied, but on increasing the supply the air found its way from under the flange of the false bottom, and none issued from the six holes at the side, not until they had been made considerably larger. The amount of air delivered by one hole in the ridge was equal to that delivered by a hole in the former apparatus.

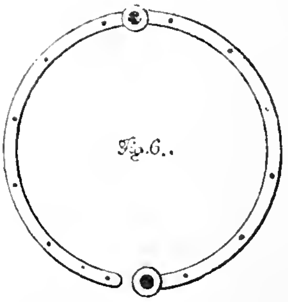

Fig. 6.

I next tried a pipe $\frac{1}{4}$-in. bore bent into a circular ring (Fig. 6). One end of the pipe was sealed, the other open end formed the inlet. There was a branch soldered on at half length of the pipe, which could be used as an inlet. Again it was found that the position of the inlet pipe did not affect the results at all.

When a small current of air was passed into this pipe, of the twelve holes which were drilled into it, only a few began to deliver. The position of these holes could not be foretold when the ring was perfectly level, but, if the ring was slightly out of level, the highest holes had the lead. On gradually increasing the air all the twelve holes could be supplied. When measuring the quantity of air delivered by each hole, it was found that the holes delivered all the same quantity, those nearest to the inlet pipe delivering no more than those furthest from it. On increasing still further the current of air, each hole delivered more and more air, all alike. Of course there was no other outlet for the air than the twelve holes. This type of apparatus is the one which can distribute any amount of air, larger than a certain minimum, which

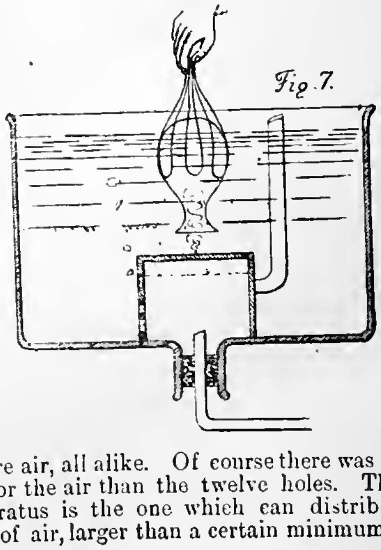

Fig. 7.

was necessary to supply all the holes. To find that minimum and how to calculate for any given case the number and size of the holes was the purpose of the next experiment.

I placed a cylindrical vessel, open at bottom, having one single hole $\frac{1}{16}$in. drilled in the centre of the top, under water (Fig. 7). On the vertical side of this vessel I drilled four holes in a vertical line ½in. apart, the first hole being ⅜in. from top of vessel.

Air was supplied and so regulated that whilst a regular stream issued from the top hole, now and then a bubble would rise from one of the side holes, the others being plugged. This side hole, by delivering bubbles, showed how far the liquid was depressed under the cylinder and served thus as a simple pressure gauge. By measuring the time necessary to deliver a given bulk of air when the level of the liquid was depressed under the cylinder by a certain amount, the following results were obtained, each measurement being repeated several times :—

No. of Experiments made.	Depression below level of vessel.	Time required for filling bulk.	Lineal Velocity in feet per second.	$56\sqrt{p} \times 0{\cdot}9$ Velocity calculated.
3	⅜in.	11 sec.	35·59	36·23
3	⅞ „	6·8 „	57·58	55·26
4	1⅜ „	5·75 „	68·10	69·50
3	1⅞ „	5 „	78·30	81·36

In this table I have added a column which contains the lineal velocity calculated by the usual ordinary formula used for finding the lineal velocity of air flowing from a vessel through an orifice into the atmosphere, the pressure in the vessel being p-inches of water above atmospheric pressure ; 0·9 being taken as coefficient of friction, etc.

It will be seen at a glance that the discharge of air from the orifice of my cylinder obeys evidently the same law, and that the discharge from an orifice under water is nearly the same as the discharge through the same orifice with the same hydraulic head would be in air. This can be proved by a simple experiment, particularly with higher velocities. If a current of air be allowed to issue from an orifice, and the velocity of the current is indicated by an anemometer, the mere submerging of the orifice under water does not alter the velocity as indicated by the anemometer, unless the depth to which the orifice is immersed becomes serious in comparison to the pressure which forces the gas out of the orifice.

It is thus evident that in order to distribute a gas properly the number and area of the holes must be such as correspond to the smallest amount of gas to be distributed. Suppose that amount known in cubic feet per second. Take the smallest pressure at which all the holes are supplied as ⅜ of a inch, then the lineal velocity of discharge is about 35ft. Divide the quantity of gas by 35 ; that will give the total area of all the holes.

It will also be evident that a false bottom is as good as the pipe system, when its flange is deep enough, which in my experimental apparatus it was not. Hence the reason why in the inverted cone the second row of holes did not deliver.

I have now communicated the mechanical principles upon which the efficient working of apparatus of the first-class depend, as far as I know them.

In my former paper I said that intimate contact might be wasted, if we did not pay sufficient attention to the chemical part of the problem.

In order to show how this is possible with apparatus of this description—*i.e.*, where the gas is allowed to rise in bubbles through a column of liquid—I will direct your attention to two special cases.

It can be shown theoretically that as the height of the column of liquid is increased the efficiency of an apparatus continually decreases. But the demonstration of the general problem is tedious, and the consideration of special cases is more interesting, and will give a better illustration of what I wish to convey.

One of the simplest operations usually carried out by means of such apparatus is the carbonating of crude soda solutions in alkali works. These solutions contain about ⅓ of the soda in the state of caustic soda, which is converted into carbonate of soda by forcing through the solution impure carbonic acid gas, either products of combustion simply, or the gases from a lime-kiln. Such a solution absorbs carbonic acid with tolerable rapidity.

If it were only the caustic alkali which contributed to the absorption, the rapidity of absorption would decrease as the caustic is gradually converted into carbonate. When the solutions are boiling hot, this is more or less the case. But when the solutions are cool, the carbonate of soda also absorbs carbonic acid, and the result is that as the caustic decreases, and the carbonate increases, the absorption remains tolerably uniform from the beginning of the operation to the end. But when bi-carbonate of soda begins to form in the solution, the rate of absorption decreases fast, as the following experiments show :—

ABSORPTION OF CO_2.

	At Beginning.	1st hour.	2nd hour.	3rd hour.	4th hour.
1.	46·4%	55·3%	52·6%	38·9%	—
	Samples of solution not analysed.				
2.	—	48·7	44·6	55·3	—
	NaHO at beginning 31·6grms. per litre. NaHO at end 0·0grm. per litre.				
3.	57·4	66·0	53·4	31·7	—
	NaHO at beginning 40grms. per litre. $NaHCO_3$ at end 9·2grms. per litre.				
4.	67·7	63·5	42·2	61·4	37·4
	NaHO at beginning 51·2grms. per litre. $NaHCO_3$ at end 6·72grms. per litre.				

This operation then represents one of the rare cases where a chemical reaction continues at uniform rate to its end.

I found that with such solutions on an average from 40 to 50 per cent. of carbonic acid could be absorbed with a given distribution under a column of two meters in depth.

Since the gas used is fuel gas, the cost of the operation is simply that of propelling the gas through the solution. Theoretically, the amount of work which must be expended to propel one cubic meter of gas through two meters of water is 1930 kilogrammeters ; and through four meters of water 3643 kilogrammeters. It does not theoretically require quite double the expenditure of work to drive the gas through four meters of water than to drive it through two only. But in practice the small difference is not worth taking into account, and we may safely take it that the cost of pumping the gas through four meters of liquid is double that of pumping it through two meters only.

If, then, four meters of liquid absorbed twice the amount of carbonic acid which two meters of the same liquid absorb, the cost of carbonating would be independent of the depth of the solution. Unfortunately, that is not so. Whilst two meters of liquid absorb 40 per cent. of CO_2, four meters absorb only about 60 per cent., so that for double the amount of work we obtain little more than 1½ times the result, and the operation becomes the more costly the deeper the column of liquid is chosen.

But immediately we put a price on the gas, however small, the aspect of the case is considerably altered.

Suppose, for instance, we had a blowing engine delivering 1000 cubic meters of gas per hour, and that this engine cost £300. At 10 per cent. interest this would amount to about 1d. per 1000 cubic meters of gas delivered. The cost of blowing for steam, etc., would be for every meter of depth of liquid 2d. per 1000 cubic meters (at the rate of ½d. a horse-power per hour).

Consequently the total cost would be for D meters depth,—

2D + 1 penny per 1000 cubic meters.

If, now, the absorption of gas is represented by the following series which I have interpolated from experiments :—

At 1 meter	22 per cent.
2 „	40 „
3 „	53 „

and the gas contain 20 per cent. by volume of pure CO_2, the cost of every 100 cubic meters pure carbonic acid gas really absorbed would be at

1 meter	2 meter	3 meter	4 meter	5 meter	6 meter
6·6d.	6·25d.	6·6d.	7·2d.	7·6d.	8·2d.

We see that under such conditions about two meters in depth gives the most economical result.

If, however, interest and depreciation include other plant, if costs have to be charged for freeing the gas from tar and sulphurous acid or other impurities, or if for other reasons the gas has a value, the result becomes still more altered.

Assuming, for instance, a charge of 10d. per 1000 cubic meters, instead of 1d., and taking otherwise similar conditions, the costs for 100 cubic meters pure CO_2 absorbed amount to for

1 meter	2 meter	3 meter	4 meter	5 meter	6 meter
27·0d.	17·5d.	15·2d.	14·0d.	13·8d.	14·0d.

which shows that under these altered conditions the most economical result is obtained at about five meters depth.

Let us consider as another example the Weldon process. Here atmospheric air is pumped through a solution of calcium chloride, holding in suspension manganese monoxide, which absorbs the oxygen of the air, and is thereby converted into di-oxide. As rapidly as the monoxide decreases, as rapidly does the rate of absorption decrease, and when about 80 per cent. of the manganese monoxide has been charged, the absorption of oxygen is very small indeed.

From some figures given in Professor Lunge's treatise, I calculate that the average absorption amounts to about 10 per cent. Weldon quotes instances where it was more, but I have seldom found it to exceed 5 per cent. on the average.

Now, when the rate of absorption is so small, the effect of doubling the depth of the solution is so nearly that of doubling the resulting absorption, that in such a case the costs of the operation continually decrease as the depth of the liquid is increased, particularly when the charges for the gas are for any reason high. Consequently, in such a case, we must use as deep columns as are practicable.

If our engineers could so construct blowing engines that a gas could be forced economically through a great depth of solution it would be a great advantage. Theoretically, the cost of propelling a gas by means of a cylinder which is not cooled through a column of 20 meters ought not to be more than about 13 times that of blowing through one meter, and with a well-cooled cylinder, it ought not to cost more to force a gas against 40lb. of pressure than six times the cost of forcing it against 4lb. of pressure.

But owing to the difficulties of leakage and noxious space it costs more and more per lb. additional pressure to force a gas against high pressures.

The efficiency of apparatus of the class I have discussed can therefore be improved very much more by attention to good blowing engines than by attending to the other points. But I think I have shown that they are worthy of attention too, particularly the rate of absorption, and if I have succeeded in making it clear that for some operations there are certain depths which are more economical than either greater or lesser, I hope I may be considered to have rendered a small service.

DISCUSSION.

Mr. **Rawson** wished to know whether Dr. Hurter had made any experiments on the shape of the orifices through which the gas passed? As far as he understood, the orifices used in Dr. Hurter's experiments were of a circular shape. He would like to know whether any square or rectangular orifices were used also? It appeared to him that, supposing the orifices had been small and circular, the bubble would pass over it, like a bridge; it would not have time to pass through that orifice, but would simply cross; whereas, if the orifice had been long and narrow, it was quite possible that it would pass through it. Also, he would ask whether nipples placed over each of the little holes would have made any difference? Then as regards the absorption of CO_2 in the caustic soda, it was shown that in the second experiment, if he remembered rightly, at the end of the second hour the amount of CO_2 absorbed had, as compared with the absorption at the end of the first hour, much diminished ere bicarbonate had been formed, whilst in the fourth experiment the amount of CO_2 absorbed had increased at the end of the third hour, and yet much bicarbonate had been formed, and he did not see how these two results agreed together.

Mr. W. P. **Thompson** asked was it a fact that if a pipe closed at the end, with a series of orifices along it, were placed very obliquely, the amount of gas evolved from each of these orifices, when full pressure was on, would be the same? He thought there should be very much more from the top orifice than there would be from any of the others, as there would be less resistance from head of water above the orifice. And with regard to the differential absorption of carbonic acid at different heights, when there was only 10 per cent. of carbonic acid in the mixture, was not the lessening effect very greatly due to the fact that through the bottom meter most of the carbonic acid was absorbed, and that as it got to the top there was a film of air all around the bubble of gas, almost clear of carbonic acid, so that it was a simple mechanical effect? Then, again, as the bubble gradually got to the top it would increase so much more in velocity. Might he ask whether an experiment was tried with pure carbonic acid?

Dr. **Kohn** said there were few manufacturers to which the subject was of greater importance than to those of coal gas. The gas had to be brought in contact with liquids in order to be washed, and he would like to point out that to a great extent this washing of the gas is purely a mechanical question, the impurities being so much more readily removed when the orifices through which the gas issues are very small, so as to break up the gas. The two special things which he wished to call their attention to were :—1st, The removal of tar. It was well known that coal gas contained benzene, etc., and many attempts had been made to recover these substances, although their removal was certainly a bad thing for the gas. In the tar-condenser of Pélouze and Audouin they adopted a principle in which the gas, by impinging on a large number of small holes and then spreading over a large surface, was readily broken up, and the benzene, etc., which was contained in the gas as a kind of mist, was then removed. This was a very efficient apparatus for the removal of tar from gas, and it showed how very much the removal of the tar in this way was a mechanical operation. In the second place, the purification of gas in the gasworks depended partly on the gas being brought into contact with liquids, and in this connection the extent to which effective washing was a mechanical question was shown by the efficiency of Messrs. Kirkham, Hulett & Chandler's scrubber-washer, the good results obtained with this apparatus being due to the large wetted surface which the gas meets. The relative amounts of washing effected by the different portions of a column of water, as pointed out by Dr. Hurter, was well illustrated in the ordinary coke-scrubbers of gasworks, which were now made much higher than formerly, the additional height being necessary to remove the ammonia satisfactorily, although by far the greater part of the removal was effected in the lower half of the column.

Mr. Carey: How fast do these discs revolve; fast, or very slowly?

Dr. Kohn: Slowly. There is no spray; they simply get wetted.

Dr. Campbell Brown said that in connection with Mr. Rawson's question it might be just as well to tell them whether the air travelled up in bubbles, as he fancied there was a reservoir of gas beneath the false bottom.

Mr. Rawson said he had not quite understood that there was a reservoir of air underneath the cone, but had supposed the air to be admitted more slowly.

Dr. Hurter said, in reply to Mr. Rawson, that they must not forget that in these experiments on the absorption of carbonic acid, the place where the inlet sample was taken was a considerable distance from where the outlet sample was taken, and it required two operators. Consequently the result of one single test could not be relied on for any argument. What he wanted to represent by the series of experiments, was that on the average there was not much difference in the rate of absorption from beginning to end. But when the solution began to contain bicarbonate of soda, it had a tension for carbonic acid (for the temperature was at least from 130—140° F.), and then the absorption decreased rapidly. The hours in the various experiments had nothing to do with each other; the third hour of one experiment could not be compared with the third of another. As regards the bubbles rushing past the holes, this was not so. The false bottom was of a certain thickness of metal, and before the water made room for the air in the holes, there must be a certain pressure of gas below the false bottom. Now in his conical false bottom the flange was not deep enough, and sufficient pressure could not be got before the air rushed past the flange. But he had made no experiments with holes of any other shape than circular. In reply to Mr. Thompson, he had tried similar experiments with an oblique pipe, and as Mr. Thompson quite correctly supposed, the highest holes delivered most air. With regard to the reason for the decrease of absorption with increased height, the gradual decrease of carbonic acid in the gas was partly the reason, but the chief reason was that the upper half of the column absorbed of the gas presented to it just as many per cent. as the lower half did. Thus, if the lower half absorbed 50 per cent. and left 50 per cent., the upper half would absorb 50 per cent. of what was left—*i.e.*, 25 per cent. of the original amount. If pure carbonic acid were employed, that would be a different thing altogether. Here the gas would remain equally rich throughout, and the absorption would be very much faster. In reply to Dr. Kohn, the removal of tar from coal-gas was an entirely different problem to the one he had been discussing where a gaseous constituent had to be removed. Without very careful experiment he would not be inclined to accept as a fact that the coke tower was so much superior an apparatus as the one Dr. Kohn had described, and which was very similar in principle to one Professor Lunge had lately proposed for hydrochloric acid gas. In reply to Mr. Carey, there always was a layer of gas under the false bottom. When the false bottom was constructed of glass, that layer could be seen.

A METHOD OF COOLING WATER FOR TECHNICAL PURPOSES.

BY PETER HART.

The consumption of 20,000 gallons of water per day for cooling purposes alone, at a rather high price per thousand, with a prospect of curtailment of quantity in consequence of continued drought, induced me to try if much of it could not be used again and again. My first effort consisted in constructing an underground reservoir, in the shape of a portion of a boiler-shell, into which the hot water was run, and from thence pumped into the ordinary high cistern from which the works obtained its supply. I thought it possible that during its travel and exposure in these cisterns it might lose sufficient heat to be again available for its original purpose, especially as it would get mixed with the water used for the steam boilers and solution purposes. This arrangement worked well for perhaps two or three days, when, in consequence of its receiving more heat than it could dissipate by its exposure, the whole works became supplied with water sufficiently hot for an ordinary warm bath. Of course, this state of things could not continue, for though well adapted for a severe frost and consequent immunity from frozen pipes, it failed to cool to the requisite degree the apparatus it was largely employed in. At this stage a compromise was entered into. As much of the hot water was pumped into the cistern as could be sufficiently cooled without deranging the works, the remainder as before being run to waste. This, though satisfactory as far as it went, was not wholly so; it was evident that could the water be sufficiently exposed to the air the object would be effected. The obvious expedient for this purpose was a shallow reservoir in which the hot water could circulate, but for this purpose no available land existed. After further consideration of the conditions, I achieved my object by means of the apparatus I am about to describe. Within the cistern itself, and which is about 20 feet square, I erected what may be aptly termed a huge gallows, the cross beam of which, placed 10 feet above the highest water level in the cistern, consisted of a wooden shoot lined with lead and firmly bolted to the uprights, which were placed 15 feet apart, the whole erection being placed so as to face the prevailing summer winds. The bottom of the shoot, was perforated with a large number of small holes along the whole length, and the delivery pipe of the pump, instead of being permitted as before to deliver its contents immediately into the cistern, was raised and compelled to empty itself into the shoot, from whence the water fell into the cistern in a series of small streams, chiefly broken into rain before reaching the cistern. Our first experiment was made in calm weather, and seemed eminently satisfactory. But winds came and found out one weak place in the scheme; a comparatively moderate one blew showers of water either into the works or into the adjoining street, unsatisfactory in either case. Fortunately this was easily obviated by the very simple expedient of nailing ⅝in. by 7in. boards horizontally from upright to upright, leaving 3in. spaces between on both sides, a space on one side being opposite a board on the other. These openings seem to be ample to permit the wind to blow through, and are otherwise an improvement, as a very gentle breeze drives the streams on to the boards, over which they trickle down, exposing thus a very large surface. The cooling power of this apparatus is very erratic, varying very much with the temperature of the air and the quantity blown through, as far as our observations go, from 20° to 35° F. of decrease of temperature. At all events it has served my purpose, but should I find next summer that it does not effect all I desire, I shall simply duplicate the arrangement and divide the pump stream into two, thus giving the water a longer exposure.

ON THE COMPOSITION OF CERTAIN COLLIERY WATERS.

BY PROF. P. PHILLIPS BEDSON, D.SC.,
Durham College of Science, Newcastle-on-Tyne.

The introduction to the notice of mineral brine springs contained in the volume devoted to the "Industrial Resources of the Tyne, Wear and Tees," prepared for the meeting of the British Association in 1863, may serve, with slight alteration, as a suitable introduction to my paper.

The first sentence reads as follows:—"The discovery of the bed of rock-salt at Middlesbrough lends additional interest to all the saline springs met with in the collieries of this district." After a lapse of 20 years or more, we may now read this sentence with but slight alteration, substituting for "discovery," the "*working* of the bed of rock-salt at Middlesbrough lends additional interest to all the saline springs met with in the collieries of this district."

The analyses also published by Dr. Richardson, Mr. Dunn, M.Sc., and others, of water-pipe deposits found in various collieries in this district have combined to make the investigation of the waters from the coal measures of the neighbourhood a matter of some interest, and interest sufficient to make it unnecessary for me to apologise for laying before you this evening the results of the analysis of two mineral waters obtained from collieries situated in the neighbouring county of Durham. Nor should the nature of the mineral contents of such waters fail to be of interest to those connected with the chemical industries of this district, as the history of the soda industry of the Tyne shows how intimate has been the association of one with the other; and, as you are aware, until within comparatively recent times a brine spring at the Birtley Colliery was worked for salt.

These facts then will sufficiently excuse my making the results of the analysis of two colliery waters conducted under my supervision the subject of a communication this evening.

WATER FROM THE REDHEUGH COLLIERY.

This water drains from the Brockwell seam and adjacent rock. The sample was collected from a sump on the 2nd West Way, into which the feeder is continuously running, and from which the water is siphoned to the shaft, a distance of about a quarter of a mile. A siphon pipe juts into the water about five yards from where the sample was taken. The temperature of the water was found to be 13° C. For this information, as also for the sample of water, I am indebted to Mr. T. O. Robson, the manager of the Redheugh Colliery.

The qualitative analysis of the residue left on evaporating this water shows it consists of chlorides of the metals, barium, calcium, magnesium, and sodium and lithium.

The method adopted in determining the quantities of these substances was briefly as follows:—A measured volume of water was taken, and in it the barium and calcium were precipitated as carbonates by means of ammonium carbonate; the carbonates were, after washing, subsequently dissolved in hydrochloric acid, and the barium converted into sulphate, the calcium being estimated in the filtrate from the barium sulphate by precipitating it as oxalate, the latter being converted into calcium carbonate and weighed as such.

The filtrate from the barium and calcium carbonates was evaporated to dryness and ignited; the residue thus obtained was dissolved in water, and the magnesium contained in it precipitated in the form of hydrate by means of baryta water. The precipitated magnesium hydrate, after filtering and completely washing, was dissolved in hydrochloric acid, the barium compound associated with it was removed by precipitation with sulphuric acid, and in the filtrate from the barium sulphate the magnesium precipitated as magnesium ammonium phosphate, weighing in the form of the pyrophosphate. The magnesium has not only been separated in this manner, but in some cases it was precipitated directly from a measured volume of the water by baryta water, the precipitated magnesium hydrate being ultimately converted into the phosphate, as described above.

The filtrate from the magnesium hydrate containing, in addition to baryta water, the chlorides of the metals sodium and lithium, the baryta was removed by precipitation with ammonium carbonate, and the filtrate evaporated to dryness and ignited leaves a residue of the chlorides of sodium and lithium, which was weighed as mixed chlorides.

The estimation of lithium has been attempted in various ways, and the results obtained are not such as to warrant any great confidence being placed in their accuracy. My experience shows that a method of estimating and separating lithium from sodium is still a desideratum. These reflections apply to those methods originally given for this purpose; but I have not yet had the opportunity of examining fully the method described by Gooch (*Chem. News*, 55, 1887, pp. 18, 29, 40, 56, 78), which depends upon the difference in solubility of lithium chloride and sodium chloride in amyl-alcohol. The experiments made by one of the students of the Durham College of Science, Mr. H. A. Hooper, certainly show that Gooch's method is more promising than any of the others, and I hope to be able to apply the method to this and other similar cases.

In the first attempt to determine the lithium, 100cc. of the water only were taken, and, after the removal of all the metals (save sodium), the lithium was separated from the sodium by precipitation as phosphate. A second attempt was made with a larger volume of water—viz., 1 litre. The lithium chloride was partially separated from the sodium chloride by treating the residue, left after evaporating the water to dryness, with alcohol, filtering from that insoluble in alcohol and washing with alcohol until the residue was freed from lithium salts, as tested by the spectroscope. The alcoholic filtrate and wash-water were next evaporated to dryness, the residue dissolved in water and the magnesium removed by precipitation with baryta water; and in the filtrate from the magnesium hydrate the barium and calcium were removed by precipitation with ammonium carbonate. The solution containing ammonium, sodium and lithium salts was evaporated to dryness and ignited. In the residue thus freed from ammonium salts, the lithium was precipitated as phosphate by sodium-phosphate in presence of caustic soda and ammonia. The directions given by Fresenius as to the mode of carrying out this method require repeated treatment with sodium-phosphate, owing to the solubility of lithium-phosphate.

The first of these methods gave 723mgrms. of LiCl per litre and the second gave 381·9mgrms. of LiCl. The want of agreement being far from satisfactory, a third attempt was made. For this purpose nearly two litres—viz., 1860cc.—of the water were evaporated to dryness. The lithium chloride was extracted from the residue by treating first with alcohol until the insoluble portion was freed from lithium salts. The residue left after evaporation of the alcohol was dried at 110—120°, reduced to a fine powder and digested for several hours with a mixture of alcohol and ether. The solution thus obtained was again evaporated to dryness, and the dried residue digested again with alcohol and ether. The residue left, after removal of the alcohol and ether, was dissolved in water, and thus a solution was obtained containing the lithium-salts, associated with some of the sodium, calcium and magnesium salts. The magnesium and calcium were removed in the manner already described, and finally a residue of lithium and sodium chlorides obtained. This residue was weighed and then dissolved in water, the solution made up to a quarter litre and the chlorine determined in an aliquot part of this solution by precipitation with silver nitrate in the usual way. From the weight of the mixed chlorides and the weight of chlorine in these, the lithium chloride has been estimated indirectly.

The result obtained in this case gives the amount of LiCl as 0·335grm. per litre, which is no doubt too low, as some of the lithium was found to have been precipitated by ammonium-carbonate with the barium and calcium salts. Still, the result lends some support to that obtained by the direct determination of the lithium as phosphate. The amount of chlorine as chlorides in the water was determined by taking 10cc. of the water, diluting it with distilled water to 100cc., and of the diluted water 10cc. were used for precipitation with silver nitrate.

The results obtained were as follow :—

From 100cc. of the water:—
0·15389grm. $BaSO_4$ = 0·0904 Ba.
1·897 „ $CaCO_3$ = 0·7588 Ca.
0·3656 „ $Mg_2P_2O_7$ = 0·079 Mg.
(Mean of two separate determinations).
5·9603grms. NaCl and LiCl.
(Mean of three separate determinations).
From 10cc. of the water :—
2·182grms. AgCl 0·539grm. Cl.
From one litre of the water :—
(1) 0·3475 Li_3PO_4 = 0·3819grm. LiCl.
Indirect determination giving.. 0·335 „
Mean = 0·358grm.

These results give the following as the amount of salts in this water :—

	Grms. per litre.	Grns. per gallon.
Barium chloride..........	1·372	96·04
Calcium chloride	21·058	1474·06
Magnesium chloride......	3·127	218·89
Sodium chloride	59·265	1148·55
Lithium chloride..........	0·358(?)	25·06(?)
	85·180	5962·60

Chlorine required .... 52·524grms. } per litre.
„ found .... 53·9 „ } per litre.

Water from the Wardley Colliery.

The second water is remarkable not only from its mineral constituents, but also from the fact that it contained a considerable quantity of gas dissolved in it, and amongst the gaseous constituents Marsh gas is to be reckoned. I am indebted to Mr. Walton Brown, of Newcastle, for directing my attention to this matter, and also my thanks to Messrs. John Bowes and Partners, the owners of the colliery, for permission to collect and examine the water ; as also for the facilities afforded for the examination of the gas given off from the water.

The history of the water is, briefly, the following : —In the early part of July, 1886, a borehole in exploring workings from Wardley Colliery touched a feeder of water which had accumulated in some old workings. The bore-hole was plugged and a tap inserted, so that the water might be run off as desired by means of a pipe to the sump at the bottom of the pit. It was soon noticed that inflammable gas was being continually given off from this water, as it passed over the flat sheets towards the sump.

Several samples of the water, collected as it issued from the pipe at the bottom of the shaft, were examined for their gaseous and mineral contents. A sample of the gas was collected by Mr. Saville Shaw, Demonstrator in Chemistry in this College, from the water at the same point. This was effected by allowing a stream of water to run through a horizontal branch of T piece made of tin-plate tubing, the vertical branch of which was attached to a bottle filled with water. The vertical branch of the T piece was divided into two parts by a piece of tin-plate, and in this way the stream of water passing through the horizontal tube was broken up, the gas given off passing into the bottle and displacing the water contained in it.

The qualitative examination of the residue left on evaporating the Wardley Colliery water showed it to contain chlorides and sulphates of iron, calcium, magnesium, sodium, and lithium ; also small quantities of carbonates of calcium and magnesium. When first collected, the water is perfectly clear and colourless, but on standing it first becomes opalescent, and gradually a brown precipitate, apparently of hydrated ferric oxide, separates out. On boiling, a deposit is formed, which is black at first and gradually becomes brown. This deposit appeared to consist at first of the magnetic oxide of iron. The method adopted in analysis need not be described in detail. It consisted first in evaporating a measured volume of the water to dryness. The residue after drying at 120° was weighed, next treated with water, and the soluble portion thoroughly evaporated by washing from insoluble matter. The insoluble matter contained ferric oxide and calcium and magnesium carbonates ; the amounts of which were estimated in the usual manner.

The soluble salts consisted of sulphates and chlorides of iron, calcium, magnesium, sodium, and lithium. The methods of separation and estimation were similar to those used in the previous case, with the exception that in the estimation of the sodium and lithium a measured volume of the water was taken in which the iron and magnesium were precipitated by baryta ; in the filtrate from these the barium and calcium salts were precipitated with ammonium oxalate, and from the filtrate the sodium and lithium chlorides were obtained by evaporation to dryness and ignition to expel ammonium salts. The weight of sodium and lithium chlorides was determined ; these were next converted into sulphates and the weight of mixed sulphates estimated. I have not attempted to estimate the lithium in this case, as my experience with the Redheugh water was not such as to invite a second essay. An indirect estimate has been made by determining the amount of SO_4 in the weighed sulphates, calculating this as sodium sulphate, and from the weight of mixed sulphates and the weight of sodium sulphate the lithium sulphate was calculated. The results were not satisfactory, which, no doubt, is to be explained by the fact that such methods are only applicable when there is a greater equality in the relative amounts of the two compounds than there was in this case.

Mr. Hooper has recently examined the mixed sodium and lithium chlorides by the method proposed by Gooch, and the results of his determinations show that there is about 8—9 grains per gallon of lithium chloride in this water.

RESULTS.—WARDLEY COLLIERY WATER.
(70cc. of water gave 6260mgrms. of solids, dried at 120°.)
From 70c.bc. of water were obtained :—

Residue soluble in water.

Ferric oxide .... 20·8mgrms. = 14·56mgrms. Fe.
Calcium carbonate .... 1294·4 „ = 517·76 „ Ca.
$Mg_2P_2O_7$..................... 228 „ = 49 „ Mg.

Residuum insoluble in water.

Ferric oxide.................. 19 mgrms. = 13·3mgrms. Fe.
Calcium oxide .... 5·3 „ = 9·1 „ $CaCO_3$
$Mg_2P_2O_7$ .... 2·8 „ = 1·51 „ $MgCO_3$

From 70c.bc. were obtained :—
Sodium and lithium sulphates=4590mgrms.=3775mgrms. NaCl.
Sodium and lithium chloride found= 3747·1mgrms.
Chlorine estimation gives 3332mgrms. per 70cc.
SO_4 „ „ 78·4 „ „ „

	Grains per gallon.	Grains per litre.
Ferrous sulphate	75·61	1·08
Calcium sulphate	43·42	0·62
Calcium chloride........	1401·49	20·021
Magnesium chloride	193·9	2·77
Sodium and lithium chlorides	3747·1	53·53
Calcium carbonates	9·1	0·134
Magnesium carbonate ..	1·51	0·021
	5472·43	58·176

Chlorine required .. ... 3319·7grains } per gallon.
Chlorine found .... 3332 „ } per gallon.

Gases contained in Wardley Colliery Water.

Several determinations have been made of the gases expelled from the water by boiling. The results show that the amount and composition of the gas varies with the time allowed to elapse between collection and examination. The gases evolved were examined in a Hempel's apparatus, and cannot therefore claim superior accuracy.

A sample of water collected on the 13th of July was examined on the 16th. The results obtained were as follow :—

664cc. of water gave 55·7cc. of gas at 17° C. and 29·64in.
This would represent 7·81cc, of gas N.T.P., from 100cc. of water.

The analysis of the gas showed it to have the following composition :—

Carbon dioxide	81·14
Marsh gas	5·2
Nitrogen	13·29
	99·63

A further examination of the gaseous contents of the same water, after it had already stood in the laboratory for four days in a partially-filled bottle, yielded the following results :—624cc. gave 41·4cc. gas at 19° and 29·56in., representing 38·4cc. at N.T.P., therefore 100 volumes of the water would give 6·15 vols. of gas. The gas was found to have the following composition :—

Carbon dioxide	79·7
Nitrogen	17·3
Oxygen	1·1
Marsh gas	1·4

These results show that not only does the water lose gas on standing, but also a change in the composition of the gas takes place.

Another sample of the water was collected by Mr. S. Shaw at the bottom of the colliery shaft, on the 19th July, and submitted at once to examination, with the following results :—664cc. of water gave 71·8cc. of gas at 19° and 29·8in., representing 66·8cc. of gas at normals ; or 100 vols. of the water will give 10·05 vols. of gas measured at normals. The gas was found to have the following composition :—

Carbon dioxide	85·9
Nitrogen	9·6
Marsh gas	4·17
Oxygen	0·55
	100·22

On the same occasion that this water was collected, Mr. Shaw also collected some of the gas given off by the water, in the manner I have already indicated. The result of the examination of this gas yielded the following :—

Carbon dioxide	10·8
Oxygen	4·4
Marsh gas	50·2
Nitrogen	34·6
	100·0

Supposing the oxygen here to represent air entering the bottle during the collection of the gas, then the volume of air would be 21·06 per 100 ; deducting this we should obtain by re-calculation the following as representing in all probability the composition of the gas given off by the water :—

Carbon dioxide	13·68
Marsh gas	63·59
Nitrogen	20·73
	100·00

These waters somewhat resemble in composition that of the brine spring at St. Lawrence Colliery, containing, according to Dr. Richardson, 4038 grains per gallon, of which 2938grs. consisted of common salt ("Industrial Resources of Tyne, Wear and Tees," p. 56).

Dr. Richardson has also shown that the water found at the Wallsend Colliery is somewhat similar in character, and he has pointed out that the constituents of this water vary in a most remarkable manner, as shown by the analysis of this water, made at two different periods some six years apart. The point raised by Dr. Richardson is of such interest that I shall again examine the Redheugh water, and should it be deemed of sufficient interest to the members, communicate the results at some future period, together with others obtained in the examination of other colliery waters.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

Steam Boiler Explosions in the German Empire during the year 1886. Chem. Zeit. **11**, 1044–1046.

During the last year sixteen steam boiler explosions took place in the German Empire. The official investigation into the causes gave the following result :—(1) Explosion of a boiler at the machine works of F. Wächter, Entin. The boiler was in a horizontal position, and provided with many heating tubes. Cause of the explosion was want of water. The taps of the water gauge were stopped up, whereby the want of water was not detected. The plates became red hot, and as soon as fresh water was pumped into the boiler, the sudden evolution of steam, which increased the pressure within the boiler rapidly from 15 to 60lb. per square inch, burst the boiler. (2 and 3) Two contiguous vertical cylindrical boilers at the iron works, Hüsten. The explosion tore one of the boilers in three pieces, one of which was completely rolled up. At the points of the fracture the iron was badly corroded, which circumstance accounts for the explosion. The second boiler was torn from its seat by the explosion of its neighbour and broke in two. (4) Explosion of a Cornish boiler at the brewery of A. Mergell. Cause of the explosion was presumably want of water. The edges at the points of fracture were porous, and had the appearance of pumice-stone. (5) Explosion of a Lancashire boiler at the Tiefbau colliery. After the explosion the second plate of the left flue was found to have burst. The fissure went right across a patch, which had been put on the second plate some two years previously. The cause of the explosion was want of water due to a strong leakage through the patch in the left flue. (6) Explosion of a Lancashire boiler at the Zocherndorf colliery. The left flue-tube was torn right across the top, at which place the iron scaled off. The right flue-tube burst only partially at the top, and was crushed somewhat flat. Corrosion of the plates, as well as an inferior quality of the iron appeared to be the cause of the explosion. (7) Explosion of a Lancashire boiler at a saw mill. The boiler burst above the

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows :—

If the price does not exceed 8d. .... ½d.
Above 8d., and not exceeding 1s. 6d. ... 1d.
" 1s. 6d., " " 2s. 4d. ... 1½d.
" 2s. 4d., " " 3s. 4d. ... 2d.

fireplace, and made a rent of 2·04 metres in the direction of the length of the flue-tube. Cause of the explosion, presumably the presence of scale on the plate over the fireplace, which must have attained such a thickness as to make the plate red hot (8) Explosion of a horizontal cylindrical boiler at the Zawadski Rolling Mills. Cause of the explosion was want of water, whereby the plate over the hottest part of the furnace became red hot and burst. (9) Explosion of an Elephant boiler at the Lindow Alcohol Distillery. The surface of the left tube showed a hole after the explosion, and the plate was particularly thin at this point. Near the hole were four patches, which were covered with a dirty scale, evidently produced by a leakage of water through the patches. The water trickling through gradually caused the corrosion. (10) Explosion of a Cornish boiler at the Beuthen Flour Mill. The flue-tube was crushed flat and torn in the middle. Cause of the explosion was evidently want of water. (11) Explosion of a horizontal boiler at the Glue Works of Jörg & König. The boiler contained a scale of 15mm. thickness, and the bluish appearance of the plates pointed to their having been red hot before the explosion. A leakage of the blow-off cock also caused want of water. (12) Explosion of a Lancashire boiler at the Marsberg Saw Mills. Both flue-tubes were crushed out of shape. The plates over the fire-bridge had burst. Cause of the explosion was want of water. (13) Explosion of a horizontal boiler at the Eschweiler Wire Works. The front of the upper portion of the boiler was completely torn away. Cause of the explosion was want of water, which had sunk to 40cm. below the low water level. (14) Explosion of an Elephant boiler at the Mühlhausen Flour Mill. The left tube burst, causing a fissure of 370mm. length and 300mm. width. The plate near the plug was very thin and corroded, and it is supposed that the plug, not being absolutely tight, allowed water to trickle through, which gradually caused a local corrosion. (15) Explosion of a multi-tubular boiler at a spinning mill. One of the boiling tubes in the second row burst, and the red coloration of the iron showed that it had been red hot owing to deficient circulation of the water, due to the length and cross section of the boiling tubes not having the right proportion to each other. (16) Explosion of a multi-tubular boiler at a paper works. The boiler was not yet at work, as the necessary pressure of 70lb. per square inch had not been obtained, owing to the draught being faulty. Suddenly an explosion took place, which broke all the joints of the tube in the tube-plate, and also bulged out the latter. It was then found that snow in the previous night had partially closed the chimney, and thus caused the fire to burn badly. By these means explosive gas mixtures may have been formed in the tubes, which were suddenly lighted on opening the fire-door.—S. H.

Klein, Schanzlin & Becker's Rotary Pumps. Chem. Zeit. **11**, 1046.

These pumps are pre-eminently suitable for pumping boiling hot, pulpy liquids, in which they are best suspended (see Fig. 1, next page). They are also extremely useful for lifting nearly dry and crumbling substances, as, for instance, the filling mass of sugar works. They then run the reverse way (Fig. 2); the mass is emptied into a hopper and forced from the bottom upwards to 12 metres. The pumps can also be used for draining shafts and wells (Fig. 3). They can be driven by a vertical shaft, as shown, and no harm is done if the pump is suspended below the water level.—S. H.

II.—FUEL, GAS AND LIGHT.

On the Rate of Consumption of Illuminating Agents and the Intensity of Light given out by the various Methods of Illumination. Journal für Gasbeleuchtung, 1887, **30**, 671.

C. Heim has compared various methods of illumination as regards their intensity and effective power from an economic point of view. The intensity was measured by a photometer of the usual construction and stated in normal candle units, the intensity of the various lights being examined both in horizontal direction and at an angle of 45° downwards. 1. *Petroleum Lamps.* The lamps were supplied with "Kaiser-oil" of 0·796 sp. gr. and yielded the following tests:—

TABLE I.

Description of lamp.	Diameter of burner. mm.	Angle with the horizontal plane.	Strength light in normal candles.	Con. of oil per hour. grms.	Consumption of oil per candle unit.	Remarks.
Circular burner	25	0°	16·1	54·2	3·37	Kaiser-oil
" "	"	45°	12·3	53·6	4·36	" "
Circular burner with plate (small)	30	0°	19·2	63·4	3·30	" "
" "	"	45	11·1	61·1	5·51	" "
Circular burner with plate (large).	62	0°	67·3	22·9	3·40	" "
" "	"	45°	33·9	22·8	6·72	" "
Kosmos Circular burner	30	0°	22·9	84·9	3·70	American Petroleum
" "	"	45°	17·8	85·5	4·80	" "
" "	"	0°	22·8	81·7	3·58	Kaiser-oil

The figures of this table show that the intensity of light, measured in the horizontal direction, from all the lamps examined is about equal. The effective power is not proportionately increased by an increased size of the lamp. Measured at an angle of 45 the intensity of light decreases with an increased diameter of the burner. The effective power of a petroleum lamp decreases considerably if the flame is not screwed up to its full height, as is shown by Table 1A.

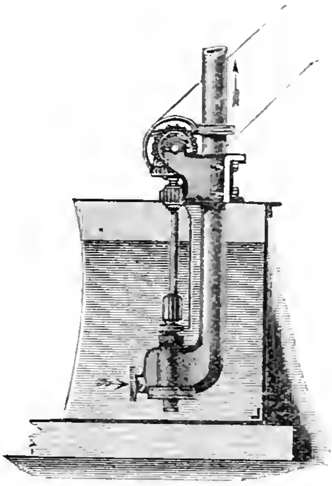

FIG. 1.

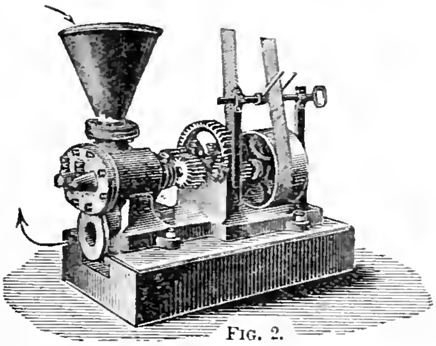

FIG. 2.

TABLE 1A.

Angle.	Intensity of Light.	Consumption of oil per hour.	Cons. per candle and hour.
0°	18·9	58·4	3·09
0°	16·8	56·0	3·33
0°	15·0	54·8	3·65
0°	12·7	50·7	3·90

Gas Lamps.—The different tests were made under equal and normal conditions. Regenerative burners were lit half an hour before testing, smaller burners a sufficient time to warm all the parts of the lamp. The combustion gases were carried away by a ventilating flue. The plane of the split burner was vertical to the photometer-axis.

It is well known that the intensity of light is considerably raised by an increase of the temperature of combustion, and the last column but one in Table II. confirms this fact. The split burner is surpassed by the Argand and the latter by the regenerative burner. Both Argand and Siemens' burner distribute the light badly, since they emit the maximum of light in the horizontal direction, whereas the Wenham lamp emits most of the light vertically downwards. The latter is therefore specially suitable for illuminating large rooms or halls, as for an equal consumption of gas its light is three and a half times as strong as that of split burners. Larger types of the Wenham lamp yielded a better result still. The Welsbach incandescent lamps are also preferable to Argand and split burners, at least as long as the incandescent body is new.

Electric Arc Lamps.—Three of the best known constructions were examined. A compound engine of 100 V. was employed as a source of the electric current. Only the tests taken at an angle of 45° can be fairly considered as representing the value of the various lamps. The intensity of light in the horizontal direction fluctuates continually, increasing and decreasing with the slightest variation in the position of the arc. By enlarging the type of lamp or increasing the strength of the current the effective power of the lamp is raised.

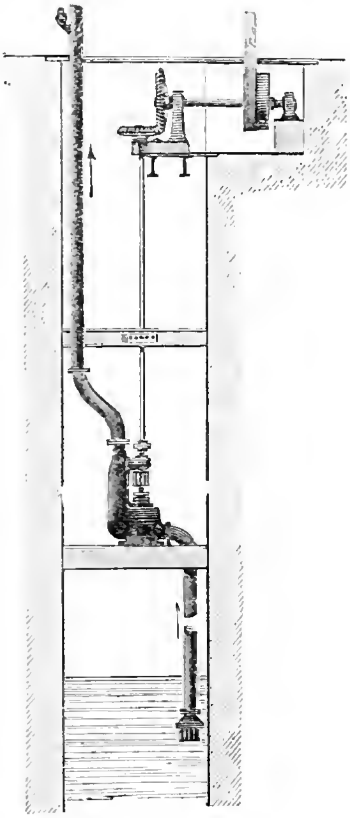

FIG. 3.

Incandescent Lamps.—Only sixteen candle power lamps were tested, as these are nearly exclusively in use. The intensity was only examined in the horizontal direction.

Magnesium Lamp.—A lamp from A. Grätzel, Hanover, was photometrically tested. It was constructed in such a manner that as many as eight magnesium ribbons of 2·5mm. width and 0·13mm. thickness could be burned at the same time. The white smoke of magnesia was carried away by a ventilating tube which was firmly connected with a reflector. To obtain the intensity of light without reflector the latter was covered with black paper. The light was measured in the horizontal direction; measurements at an angle of 33° showing a decrease in intensity of 25 per cent.

The intensity of light for one ribbon is greatest when only one ribbon is being burned; it sinks not inconsiderably if more are lit. The consumption of magnesium per hour amounts with 8 ribbons to 0·134kilo. One kilo. costs 45s., consequently, the cost of one hour's burning is about 6s.

Latterly, an improved construction of lamp reduces the cost of one hour's burning to 4s. 6d. But even at this price the light is far too expensive to enter into competition with gas or the electric light. The lamp is easily handled and carried about. It can be lit with a match and put out quickly. It is, therefore, most suitable for signalling, photographic, theatrical and similar purposes.—S. H.

Improvements in Apparatus for the Manufacture of Gas from Fluid Hydrocarbons. A. G. Meeze, Redhill. Eng. Pat. 12,340, Sept. 29, 1886. 1s. 1d.

Within an ordinary gas retort, heated by a firebox of the usual construction, is placed an inner retort of considerably less diameter and preferably of thin wrought iron, the outer one being of fireclay. Within the outer retort and attached to the doorplate, in order to be easily removable, is placed a superheating steam coil. Both retorts are packed with fireclay "deflectors" or surfaces, so arranged as to promote concussion and impact among the gaseous particles travelling through the retorts. In operation, steam from the superheater is made to drive oil through an injector into the inner retort. Here decomposition takes place, promoted by the presence of the deflectors. The gas evolved then passes from the inner to the outer retort, where, encountering a greater heat, it is fixed and rendered homogeneous, and whence it passes by an ascension-pipe in the front to the hydraulic main. The inventor's claim refers mainly to the use of the deflectors. Full drawings are attached.

—A. R. D.

An Improved Continuous Process for the Purification of Coal Gas from Sulphur Compounds, by which the Sulphur is Recovered. C. Estcourt, Manchester, H. Veevers, Dukinfield, and M. Schwab, Manchester. Eng. Pat. 15,007, Nov. 18, 1886. 8d.

The inventors propose to eliminate the sulphur compounds (chiefly sulphuretted hydrogen) from coal gas, by bringing it into contact with sulphurous acid, either alone in aqueous solution or in the presence of the carbonates, chlorides or sulphates of the alkalis or alkaline earths; or of hydrochloric acid and salts containing sulphurous acid. When any of these various salts are present, practically the whole of the sulphur is precipitated, which is far from being the case when sulphurous acid is used alone. The process is preferably carried on in a scrubber, divided into a number of chambers, so connected that the course of the gas is made as tortuous as possible. Each chamber is provided with a set of blades, brushes or other suitable contrivance, mounted on a revolving shaft. At each revolution, these dip into the washing liquid contained in the lower part of the scrubber and constantly present wet surfaces to the passing gas. The process is a continuous one, the liquor after leaving the scrubber being again charged with sulphurous acid in a coke or other absorber and used for purifying over again.—A. R. D.

Improvements in the Method of and in Apparatus for the Complete Purification of Coal Gas by Concentrated Liquid Ammonia, and in the Recovery of Sulphur and Ammonia for the Manufacture of Sulphuric Acid and Ammonium Sulphate. J Hammond, Lewes. Eng. Pat. 8348, June 24, 1886. 8d.

This specification, which is unsuited for useful abstraction, contains four sheets of drawings. The claims are (1) the use of a series of chambers, whereby the passing gas can be made alternately hot and cold in the presence of free ammonia and vapour, for the purpose of suddenly condensing therefrom much of its impurity, which may then be carried off by the strong condensed alkaline liquors; (2) the preparation and use of coke and iron, with the admission of a regulated quantity of air (carburetted or otherwise), to keep the same chemically active upon the passing gas in the presence of liquid ammonia or water.—D. B.

An Apparatus for Projecting Oil or other Fuel into Furnaces in the form of Spray. C. A. Sahlstrom, Aberdeen. Eng. Pat. 15,076, Nov. 19, 1886. 8d.

This apparatus is an improvement on that described by the patentee in the specification of Eng. Pat. 14,535 of 1886 and may be described as an injector consisting of a central passage for superheated steam, an outer annular passage for hot air and an intermediate annular passage for oil. All these deliver into a mouthpiece with a contracted throat. The apparatus is made to swing on a trunnion socket, so that it can readily be fixed in position for working and as readily allowed to fall back from the furnace firebox when not required.—A. R. D.

An Improved Method of and Apparatus for Generating Gas for Illuminating, Heating and Metallurgical Purposes from Liquid Hydrocarbons. R. B. Avery, New York, U.S.A. Eng. Pat. 8953, June 23, 1887. 11d.

This is a process for generating gas by passing oil and superheated steam through heated retorts. The retorts and superheaters are packed with cones (of iron or fireclay), having serrated or perforated flanges, and are so disposed as to present their apices to meet the current of gas. These cones have the effect of finely dividing the passing vapours and greatly economising the heating power of the retort. The use of an exhauster is recommended, both to prevent back pressure in the retorts and also to draw in a certain amount of air, which considerably improves the quality of the gas. The specification is accompanied by nine drawings.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Vaselin. G. Vulpius. Pharm. Post, 1887, 308.

The author comes to the conclusion that the German vaselin has become purer and better from year to year, whilst the quality of the American product has continually deteriorated and that quite apart from the purity, which is there never greatly aspired to, the consistency of the American article is also inferior to the German.

—G. H. M.

Occurrence of Alkaloid-like Bases in Paraffin Oil. A. Weller. Ber. 20, 2097—2099.

Bandrowski having recently established the existence of bases in Galician petroleum, the author thought it desirable to publish the results of an investigation on the so-called yellow oil, obtained in the manufacture of Saxon petroleum, from which he some time ago isolated basic substances. The separation was effected by shaking the oil with dilute sulphuric acid, precipitating with caustic soda, extracting with ether, re-dissolving and re-precipitating several times, finally subjecting the product to distillation. The bases thus obtained form a colourless oil having a sp. gr. of 0·98—0·99. They have a very unpleasant odour, assume a dark colour on exposure to the light and do not solidify at 11°. They are sparingly soluble in water, but freely soluble in alcohol, ether and chloroform. They contain nitrogen, but are free from oxygen and sulphur. Treatment with potash causes the evolution of strongly alkaline vapours, which are, however, free from ammonia. Bromine and methyl iodide react with the bases dissolved in chloroform, forming non-crystalline oily products. Unsuccessful attempts were made to isolate the bases by means of fractional distillation, the product obtained after several fractionations boiling between 220° and 260° without the temperature remaining constant at any one point. Several salts were prepared. The most characteristic salt is the oxalate, which crystallises in nacreous scales sparingly soluble in water and ether, but readily soluble in alcohol, chloroform, benzene and petroleum spirit.—D. B.

Isomeric Change in the Phenol Series. A. R. Ling. J. Chem. Soc., 1887, 147—152 and 782—794.

The first portion of the author's experiments were devoted to the action of bromine on the dibromonitrophenols, with the view of obtaining, if possible, some explanation of the isomeric change of dibrom-*ortho*-into dibromo-*para*-nitrophenol (Armstrong, *J. Chem. Soc.* 1875, 520).

When either of the dibromonitrophenols is heated with bromine and water, the chief product is tetrabromoquinone thus :—

$$C\ H_2Br_2(NO_2)OH + 4Br_2 + 2OH_2 =$$
$$C_6Br_4O_2 + 6HBr + HNO_3$$

Several 10grm. quantities of dibromonitrophenol (m.p. 117°) were heated in a water bath with one molecular proportion of bromine and about 40cc. water for several hours. The products were exhausted with potassium carbonate solution and the tetrabromoquinone separated by filtration.

From the filtrates the potassium salts of the following compounds were obtained :—

	M.P.
O-bromodinitrophenol	116°
O-bromo-para-nitrophenol	102°
Dibromo-para-nitrophenol	141°

The same compounds were obtained in a similar experiment made with dibromo-*para*-nitrophenol.

It would seem that the formation of tetrabromoquinone involves the partial debromination of the dibromonitrophenol, the resulting brom-*ortho*-nitrophenol then undergoing isomeric change: the bromo-*para*-nitrophenol thus produced is in part converted into bromodinitrophenol by the nitric acid resulting from the NO_2 displaced, and in part into dibromo-*para*-nitrophenol.

The second portion of the experiments relates to the action of bromine on the dichloronitrophenols, and on *p*-chlor-*ortho*-nitrophenol.

Dichloro-*ortho*-nitrophenol (m p. 123°) is not converted into its isomeride when heated with bromine and water under the conditions above described, but is decomposed, yielding chlorotribromoquinone in accordance with the following equation :—

$$C_6H_2Cl_2(NO_2)OH + 4Br_2 + 2OH_2 =$$
$$C_6ClBr_3O + 5HBr + HCl + HNO_3$$

Chlorotribromoquinone crystallises from glacial acetic acid in glistening yellow scales; the quinone forms colourless needles, melting at 234°; and the diacetyl compound colourless prisms, melting at 262°.

Chlorotribromoquinone treated with a 4 per cent. solution of potash is decomposed, giving rise to the potassium salt of chlorobromanilic acid ($C_6ClBr(OK)_2O_2$, $2H\ O$), described by Krause (*Ber.* **12**, 47).

Dichloro-*para*-nitrophenol (m.p. 125°) yields *m*-dichlorodibromoquinone, described by Krause (loc. cit.), when heated with bromine and water, thus :—

$$C_6H_2Cl_2(NO_2)OH + 4Br_2 + 2OH_2 =$$
$$C_6Cl_2Br_2O_2 + 6HBr + HNO_3$$

P-chlor-*ortho*-nitrophenol (m.p. 87°) was dissolved in glacial acetic acid and treated with one molecular proportion of bromine at the ordinary temperature. The resulting chlorobromonitrophenol crystallised from alcohol was found to melt at 125°. This compound, heated with four molecular proportions of bromine and water, was entirely converted into tetrabromoquinone, and was therefore *p*-chloro-*ortho*-bromo-*ortho*-nitrophenol.

$$OH : NO_2 : Cl : Br = 1 : 2 : 4 : 6.$$

The potassium salt crystallises in dark red, anhydrous needles, and the calcium salt in orange-red plates of the composition $(C_6H_2ClBrNO_3)_2Ca,3H_2O$.

P-chloro-*ortho*-nitrophenol dissolved in glacial acetic acid and the solution, after boiling for half an-hour with one molecular proportion of bromine, left for some hours to cool, yielded a compound isomeric with the above, melting at 119°, and giving a potassium salt in red anhydrous plates, and a calcium salt of a somewhat darker colour than that of *p*-chloro-*ortho*-bromo-*ortho*-nitrophenol, and containing 7mols. of H_2O. Heated with 4 molecular proportions of bromine and water, chlorotribromoquinone was obtained. The compound was therefore *o*-chloro-*para*-bromo-*ortho*-nitrophenol.

$$OH : NO_2 : Br : Cl = 1 : 2 : 4 : 6.$$

The constitution has been further proved by preparing *o*-chloro-*para*-bromo-*ortho*-nitrophenol from *p*-bromo-*ortho*-nitrophenol (m.p. 88°) and chlorine, and comparing it and its salts with the compounds last described. The melting point of pure *o* chloro-*para*-bromo-*ortho*-nitrophenol is 117°.

It has also been found possible to convert *p* chloro-*ortho* - bromo - *ortho* - nitrophenol [$OH : NO_2 : Cl : Br = 1 : 2 : 4 : 6$] (m p.125°) into *o*-chloro-*para*-bromo-*ortho*-nitrophenol [$OH : NO_2 : Br : Cl = 1 : 2 : 4 : 6$] (m.p. 117) by heating the former with a small quantity of bromine.

The change takes place, however, with much less ease in the last-named case than when *p*-chloro-*ortho*-nitrophenol is brominated at the higher temperature. This is possibly because it occurs simultaneously with the exchange of hydrogen for bromine. Di-halogen derivatives of *o*- and *p*-nitrophenol being incapable of further substitution might be expected to behave somewhat indifferently towards reagents. No other compound being formed, there can be no doubt whatever that it is a case of true intramolecular change.

Improvements in the Manufacture of Carbon and in Apparatus employed therein. A. Jacquelain, Paris, France. Eng. Pat. 2566, Nov. 11, 1859. Second Edition. 8d.

It is proposed to manufacture carbon from tars and heavy oils distilled from coal, schist, peat or other volatile organic matter. The tar is heated in a boiler and the vapours generated therein are led into a horizontal earthen retort heated to redness. The retort is connected with two vertical cast-iron receivers. The deposits in the retort are removed by means of a rake. A pipe is connected to the second receiver, by which the gas, as well as such carbon compounds as may have escaped decomposition by the heat, and the volatile products are led off to be utilised for heating purposes. The inventor also claims means for improving carbon produced in gas retorts and the preparation of a hard carbon.—D. B.

A New and Improved Method for the Distillation of Coal Tar, the Oils from Coke Ovens and other similar Fluids. H. Ellison, Cleckheaton, and G. E. Davis, Manchester. Eng. Pat. 13,929, Oct. 30, 1886. 8d.

The vapours from the tar or oil still are passed through coils of piping, placed in a closed boiler of sufficient capacity to contain at least one full charge of liquid for the still. This boiler being previously filled with cold tar or oil to be distilled, the hot vapours coming from the still will bring its contents to a state of quiet ebullition, so that by the time the working of the still is completed, the water and more volatile constituents of the tar in the boiler will have been expelled and condensed in a suitable manner. When the residual pitch has been run out from the still, the latter is immediately charged with the hot tar from the closed boiler and a heavy fire started, as there is no danger of the tar boiling over. The boiler is then filled up quickly with a fresh supply of cold tar or oil and the operation repeated.—D. B.

Improvements in the Destructive Distillation of Shale and other Minerals and in Retorts therefor. R. B. Tennent, Coatbridge. Eng. Pat. 15,772, Dec. 2, 1886. 11d.

This specification, to which two explanatory sheets of drawings are attached, has reference to an improved mode of arranging gas-heated retorts for the distillation of shale and other minerals, whereby great saving of heat is said to be obtained by utilising the heat of the waste gases, after heating the retorts, for heating the air to a very high temperature before reaching the gas, also in superheating the steam for treating the shale within the retort. The waste gases passing into the main flue leading to the chimney may also be made to heat a steam boiler erected over a continuation of the flue beyond the whole range of retorts.—D. B.

IV.—COLOURING MATTERS AND DYES.

Tabular Arrangement of the Artificial Organic Colouring Matters. Gustav Schultz and Paul Julius.

In view of the fact that the reprint of these tables is prohibited, as also the right of translation, the reader is referred to the *Chemische Industrie*, 1887, Nos. 8, 9, 10 *et seq.* The appearance in this Journal of the first part of this tabulated matter was the result of an unfortunate oversight.

Researches on the Constitution of Azo- and Diazo-derivatives. II. Diazoamido-Compounds (continued). R. Meldola and F. W. Streatfeild. J. Chem. Soc. 1887, 434—451. (See also this Journal, 1887, 283.)

In this paper the authors describe the results of their experiments upon the decomposition of dinitro-diazoamido-compounds by cold hydrochloric acid. The method adopted is to allow the diazo-compound to stand in contact with excess of the cold concentrated acid till decomposition has taken place, and the whole or nearly the whole of the substance has passed into solution. The latter then contains only a diazo-chloride and an amine, so that on dropping the acid solution into a solution kept well cooled, containing the necessary quantity of β naphthol dissolved in sufficient caustic soda to keep the whole alkaline after mixing, the diazo-chloride at once forms an azo-β-naphthol compound, while the amine is set free. A mixed precipitate of amine and azo β-naphthol compound is thus obtained, and from this dilute acid dissolves out the amine, leaving the azo-compound, which can be identified by its melting point and other characteristics. The reactions are illustrated by the following equations:—

$$(1)\ NO_2.C_6H_4.N_2.NH.C_6H_4.NO_2 + 2HCl = NO_2.C_6H_4.N_2.Cl + NO_2.C_6H_4\ NH_2,\ HCl$$

$$(2)\ NO_2.C_6H_4.N_2.Cl + NO_2.C_6H_4.NH_2,\ HCl + C_{10}H_7.ONa + NaOH = NO_2.C_6H_4.N_2.C_{10}HO_9.H + NO_2.C_6H_4.NH_2 + 2NaCl + OH_2$$

The symmetrical compound, paradinitro-diazoamidobenzene (prepared by the action of nitrous acid upon *p*-nitraniline) by this means is shown to be resolved by cold hydrochloric acid into paranitro-diazobenzene chloride and paranitraniline. The unsymmetrical compound (m.p. 211°) described by the authors in their previous paper, and prepared by the action of diazotised *para*-nitraniline on *m*-nitraniline or *vice versâ* is resolved by the cold acid into a mixture of *p*- and *m*-nitraniline and *p*- and *m*-nitro-diazobenzene chloride. The symmetrical dimetadinitrodiazoamidobenzene (m.p. 194°) obtained by the action of nitrous acid on metanitraniline is resolved into *m*-nitraniline and *m*-nitrodiazobenzene chloride. The method has also been applied to the ethyl-derivatives with the following results: The ethyl-derivative of the dipara-compound (m.p. 191—192°) gives *p*-nitrodiazobenzene chloride and ethyl *p*-nitraniline. The corresponding dimeta-compound gives *m* nitro-diazobenzene chloride and ethyl *m*-nitraniline. The ethyl-derivative (m.p. 148°) prepared by the direct ethylation of the unsymmetrical compound of m.p. 211° behaves like the latter, giving a mixture of the two nitro-diazo-chlorides and the two ethylnitranilines. The ethyl-derivative (m.p. 174—175°) obtained by the action of diazotised *m*-nitraniline on ethyl-*p*-nitraniline is resolved into *m*-nitro-diazobenzene chloride and ethyl-*p*-nitraniline. The isomeric compound (m.p. 187°) prepared by the action of diazotised *p*-nitraniline on ethyl-*m*-nitraniline is resolved into *p* nitro-diazobenzene chloride and ethyl-*m*-nitraniline. A more thorough investigation of this last ethyl-derivative has led the authors to the conclusion that it is a true diazo-amido-compound, this being shown by its decomposition by cold acid, as above described, as well as by its products of reduction (*p*-phenylenediamine and ethyl-*m* phenylenediamine). The possibility of this compound being an amido-azo-compound having been thus disproved, the authors point out that the existence of three isomeric ethyl-derivatives is quite inexplicable on the generally received formula of the diazo-amido-compounds, and they propose as an alternative expression for the *mixed* diazo-amido-compounds the formula:—

in which the aromatic radicles X and Y are triadic in function, in the same manner that phenyl is supposed to be tetradic in quinone when this compound is written according to Fittig's view as a double ketone:—

$$C_6H_4 \begin{cases} O \\ O \end{cases}$$

In the paper the authors describe a number of metallic derivatives in which the H of the NH group is replaced by silver, copper, cadmium, cobalt and nickel, the general formula of these compounds being:—

$$NO_2.C_6H_4.N_3M'.C_6H_4.NO_2.\ (NO_2.C_6H_4.N_3.C_6H_4.NO_2)_2M''.$$

Further investigations to test the generality of the conclusion as to the existence of three isomeric alkyl derivatives are in progress. The theoretical aspect of the question has been discussed in a paper published by one of the authors in the *Philosophical Magazine* for June, 1887 (p. 513).—R. M.

Two β-naphthylaminesulphonic Acids. S. Forsling. Ber. 20, 2099—2106.

In a previous communication (this Journal, 1886, 481) the author described the preparation of a β-naphthylamine-sulphonic acid by the action of concentrated sulphuric acid on β-naphthylamine. Further investigation has shown that this acid is not pure, but contaminated with two isomerides, of which one is identical with Broenner's acid, whilst the other is designated as 1 and 2, being respectively identical with Dahl's acids 1 and 3 (Ger. Pat. 29,084, March 2, 1884). A fourth acid, perhaps identical with the δ-acid (this Journal, 1887, 593), is produced in small quantity only. These acids were isolated by repeated fractional crystallisation of the calcium salt.

β-naphthylaminesulphonic Acid I.—$C_{10}H_6.NH_2SO_3H$ is almost insoluble in water and alcohol. Its salts form well-defined crystals, which are readily soluble in water, yielding solutions having blue fluorescence. They can be heated to 180° without decomposition, excepting the silver and copper salts. The corresponding *diazo-naphthalenesulphonic acid* $C_{10}H_6N_2SO_3$ forms a greenish-yellow indistinctly crystalline powder. It is converted into β-naphtholmonosulphonic acid (Bayer's acid) when boiled with acidified water. On heating its potassium salt with phosphorus pentachloride *δ-dichloronaphthalene* $C_{10}H_6Cl_2$ is obtained, melting at 61·5°.

β-naphthylaminesulphonic acid II.—$C_{10}H_6.NH_2.SO_3H$ dissolves in about 1300 parts of water, and is almost insoluble in alcohol. Its salts show great similarity in properties to the corresponding salts of the I. acid. The diazo sulphonic acid forms a green micro-crystalline powder. On boiling with strong hydrochloric acid a chloronaphthalenesulphonic acid is obtained, the potassium salt of which on treatment with phosphorus pentachloride yields *γ-dichloronaphthalene*, melting at 48°.

—D. B.

Ruberythric Acid. C. Liebermann and O. Bergami. Ber. **20**, 2241—2247.

HAVING obtained a large sample of Caucasian madder roots (of 1886 harvest), the authors repeated the investigation of the above acid, to test the accuracy of the results obtained by Rochleder, Schunck, and E. Kopp. They obtained by a process described in the abstract following this, about $\frac{1}{15}$ per cent. of the weight of the roots of pure ruberythric acid, forming lemon-yellow silky needles, melting at 258—260°. It is readily soluble in hot water, crystallising well on cooling; less soluble in alcohol, and almost insoluble in ether and benzene. On boiling with either acids or alkalis it splits up into alizarin and grape-sugar. It does not form lakes with mordants, nor does it ferment with yeast. Its Ba, Sr, and Ca salts form beautiful red precipitates from boiling aqueous solutions.

Schunck and Rochleder admitted the possibility that rubianic and ruberythric acids might be identical substances, and careful comparison of the two has proved the correctness of this theory. The authors compared their glucoside with a sample of rubianic acid prepared by the late Dr. H. Römer, in Dr. Schunck's laboratory. The results of the analysis of the free acids, and of their Ba and K salts, correspond better to the formula of Graebe and Liebermann—viz., $C_{26}H_{28}O_{14}$, than to that of Rochleder—viz., $C_{20}H_{22}O_{11}$. The latter formula is rendered more improbable, because according to his equation the decomposition of the glucoside into alizarin and sugar takes place under dehydration of the molecule: $C_{20}H_{22}O_{11} = H_2O + C_{14}H_8O_4 + C_6H_{12}O_6$, whilst usually such decompositions are effected by hydration, which also is the case in the equation proposed by Graebe and Liebermann: $C_{26}H_{28}O_{14} + 2H_2O = C_{14}H_8O_4 + 2C_6H_{12}O_6$. As further proof in favour of this equation, the ruberythric acid was dissolved in cold concentrated sulphuric acid, this solution diluted with four times its weight of water was then heated on a boiling water bath for one hour, and, after further dilution, for other two hours; the amount of alizarin obtained was 43 per cent., whilst the equation requires 42·5 per cent. However the decomposition in like manner of the *Octo-acetylruberythric acid* $C_{26}H_{20}(OC_2H_3O)_8O_6$ and quantitative determination of the alizarin, grape-sugar, and acetic acid formed proved beyond doubt the identity of the two bodies, the reaction being as follows: — $C_{26}H_{20}(OC_2H_3O)_8O_6 + 10H_2O = C_{14}H_8O_4 + 2C_6H_{12}O_6 + 8C_2H_4O_2$. The above acetyl-compound is readily formed by the usual method by means of acetic anhydride and acetate of soda; it forms bright yellow needles, soluble in cold glacial acetic acid, soluble with difficulty even in hot alcohol, and insoluble in water. It melts at 230°.

The constitution of ruberythric acid is usually expressed by the formula

$$C_{14}H_6O_2\left\langle\begin{array}{l}O.C_6H_7O.(OH)_4\\ O.C_6H_7O.(OH)_4\end{array}\right.$$

in which both phenol-hydroxyl-groups are combined with grape sugar, and which admits quite well of the formation of an octo-acetyl-compound. However, the formula

$$C_{14}H_6O_2\left\langle\begin{array}{l}O.C_{12}H_{14}O_3(OH)_7,\\ OH\end{array}\right.$$

admits this equally well, and explains better why ruberythric is a strong *mono*-basic acid, decomposing carbonates, and even, when heated, acetates of the alkalis. The fact that it does not form lakes with mordants, which might be urged in favour of the former formula, loses its significance, since one of the authors has shown that substitution in only one hydroxyl-group destroys the dyeing property of alizarin. However, it necessitates what is not yet proved thoroughly, that the sugar combined with the alizarin should be a *Diose* (C_{12} sugar-group), which on decomposition must yield grape sugar.—T. L. B.

Examination of Caucasian Madder. O. Bergami. Ber. **20**, 2247—2251.

THE madder was sun-dried, and contained about 6 per cent. of pure colouring matters (an exceptionally large amount, the average being about 2 per cent.); 10 per cent. of crude colour was obtained by extracting 200grms. of dried root with boiling alcohol (4 litres) containing a little HCl, concentrating the solution, and then precipitating the colour with water. It contained also 7 per cent. of cane sugar. The roots were first well dried at 80—90° and then pulverised. The author's object being to obtain the glucosides, he found the best method was extraction by means of alcohol, which required to be absolute, as otherwise the yield was smaller. Twenty kilos. of madder were taken and 180 litres of alcohol used. At a time, 1kilo. of the powdered roots was cohobated with 8—9 litres of absolute alcohol for 2—3 hours; the solution filtered whilst hot and evaporated to $\frac{1}{4}$—$\frac{1}{3}$ of its volume. On quickly cooling this extract 50—60grms. of a yellowish-brown crystalline body were obtained, forming the crude glucosides for subsequent treatment. On further distilling off the alcohol from the filtrates, from 15—30grms. of crude cane sugar crystallised out from the mother liquors, of which 30—40grms. of crude colouring matters were thrown down by the addition of water. The crude glucosides thus obtained were dissolved in about 5—6 times the quantity of water, the solution treated with a small excess of lead acetate and filtered from the brown precipitate of lead salts of colouring matters. On adding sugar of lead to the filtrate, a cinnabar-red precipitation took place. This precipitate after filtration and washing, was decomposed under water with SH_2 and the lead sulphide boiled out with water and filtered gave a deep yellowish-red solution of ruberythric acid. This was then again thrown down as barium salt in the form of dark cherry-red flakes, by the addition of alcohol and baryta-water. The well-washed barium salt by solution in dilute acetic acid and filtration was freed from a tarry-resinous substance, thereupon neutralised with ammonia, and the solution again precipitated with lead acetate. The now bright red precipitate on decomposition with H_2S and extraction of the lead sulphide with water gave a clean, golden-yellow solution, from which, on evaporation, the ruberythric acid crystallised in the form of fine lemon-yellow needles, melting at 258°. The yield was about $\frac{1}{15}$ per cent. of the weight of madder worked up.—T. L. B.

Galloflavin. R. Bohn and C. Graebe. Ber. **20**, 2327—2331.

THE preparation of this yellow dye-stuff is effected by subjecting gallic acid to atmospheric oxidation at a low temperature in the presence of a small amount of alkali; the best results being obtained in an alcoholic solution of potash (this Journal, 1887, 437). Galloflavin has the probable composition $C_{13}H_6O_9$. It crystallises in greenish-yellow leaflets, is sparingly soluble in water, alcohol and ether, more readily soluble in glacial acetic acid and aniline. Unsuccessful attempts were made to obtain a reduction product. The potassium salt $C_{13}H_4O_9K_2$ is a crystalline body which is insoluble in alcohol and cold water. Galloflavin yields insoluble lakes with metallic oxides. Alumina gives a greenish-yellow colour. Alumina in the presence of a salt of tin gives a yellow colour, whilst the yellow chrome lake is said to be exceedingly fast to light and soap. The acetyl compound crystallises from benzene in white needles, melting at 230°. It is freely soluble in glacial acetic acid and chloroform, but does not dissolve readily in alcohol and ether.—D. B.

Alkannin. C. Liebermann and M. Römer. Ber. **20**, 2428—2431.

THE colouring matter of the alkanna root called, "alkannin," was described by Pelletier more than seventy years ago, and has frequently been investigated, without, however, any satisfactory solution being arrived at as regards the group of colouring matters to which it belongs. Carnelutti and Nasini (*Ber.* **13**. 1514) obtained the formula $C_{15}H_{14}O_4$ from their analytical results, and stated that this body contains two hydrogen atoms which may be displaced by acetyl. As alkannin produces a variety of colours with mordants—resembling quinalizarin in this respect—and the blue solution obtained with alkali exhibits a spectrum similar to that yielded by alizarin, the authors undertook an investigation of this colouring matter. For its preparation alkanna roots were extracted with petroleum spirit, the extract was then digested with dilute alkali, filtered, and the blue solution precipitated with hydrochloric acid. The dye was further purified by solution in ether. It formed a dark red non crystalline mass. The results of analyses point to one of the following formulæ: $C_{15}H_{12}O_4$ or $C_{15}H_{14}O_4$. When alkannin is passed over zinc dust heated to redness methylanthracene is produced, a circumstance which appears to show that this compound is a derivative of methylanthracene, probably the dihydroquinone, or its dihydride. This point, however, requires further investigation.—D. B.

Azines of Chrysoquinone. C. Liebermann and O. N. Witt. Ber. **20**, 2442—2444.

THE azine reaction of the diketones and diamines being generally applicable the authors have studied its behaviour with chrysoquinone. *Chrysotoluazine* $C_{25}H_{16}N_2$ was obtained by treating chrysoquinone with orthotoluylenediamine. It crystallises in small gold-coloured needles, giving a dark violet solution with strong sulphuric acid. *Chrysonaphthazine* $C_{28}H_{16}N_2$ was prepared from chrysoquinone and orthonaphthylenediamine. It forms a yellow microcrystalline powder. The formation and properties of the azine derivatives confirm the analogy of chrysoquinone with phenanthrenequinone; chrysoquinone is therefore naphthylenephenylenediketone. Pyrene does not form azine derivatives. Pyrenequinone gives a large amount of tarry matter, in which respect it resembles β-naphthaquinone.—D. B.

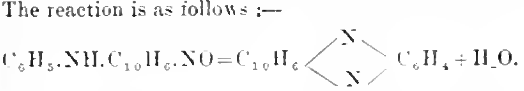
On Nitrosamines and Nitroso-bases. III. O. Fischer and E. Hepp. Ber. **20**, 2471—2478.

By the action of alcoholic HCl upon β naphthylethylnitrosamine two substances are obtained, according to the method used. (*Ber.* **20**. 1248.)

1. Equal parts by weight of β-naphthylethylnitrosamine and absolute alcohol are mixed together and cooled by ice, and then, in two portions, one part of alcoholic HCl is added, the mixture being then allowed to stand in ice, with occasional stirring, for about three hours. The solution is then poured into water, filtered from unchanged nitrosamine and the nitroso-base precipitated by ammonia. The *α-nitroso-β ethylnaphthylamine* $NO.C_{10}H_6NH.C_2H_5[NO:NH.C_2H_5=1:2]$ thus obtained forms green prisms, which crystallise from benzene in the form of flat tables, melting at 120—121°. Its salts are easily soluble, the hydrochloride and the sulphate form orange solutions, from which a yellowish white nitrosamine precipitates on the addition of a nitrite. On reduction with tin and HCl, or simply warming to 10—15° with alcoholic HCl, it is converted into the hydrochloride of the anhydro-base *ethenyl α-β-naphthylenediamine* $C_{10}H_6 <\genfrac{}{}{0pt}{}{N}{NH}> C.CH_3$.

2. This is obtained by treating six parts of the first named nitrosamine with one part of absolute alcohol and two parts of alcoholic HCl, and allowing the mixture to stand for some time at the ordinary temperature. The nitrosamine dissolves slowly, and in about four hours' time round masses of crystal appear. These consist for the most part of the hydrochloride of the anhydro-base and two by-products, separable by alcohol from each other. This hydrochloride $C_{12}H_{10}N_2HCl+2H_2O$ is soluble with difficulty in water, and forms fine colourless needles. The anhydro base is identical with that obtained by Liebermann and Jacobsen.

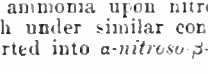
3. In a previous paper the authors hoped to obtain phenazines from certain nitroso bases by the action of dehydrating agents. They have since succeeded in obtaining Witt's naphthophenazine (this Journal, 1887, 505) by the action of alcoholic HCl on β-phenylnaphthylnitro-amine. 20grms. of finely ground nitrosamine are mixed with 200grms. of absolute alcohol, 40grms. of alcoholic HCl added whilst well cooling, and the mass allowed to stand overnight. The clear yellow solution is poured into water, the precipitated tar separated from the solution, and allowed to stand for a few hours with cold dilute sulphuric acid (1:3). The acid solution is thereupon drawn off, and the tar boiled up a few times with dilute sulphuric acid. The united acid filtrates on being poured into much water, precipitate the phenazine as a yellowish-white powder, melting at 142°. The reaction is as follows:—



$$C_6H_5.NH.C_{10}H_6.NO=C_{10}H_6<\genfrac{}{}{0pt}{}{N}{N}>C_6H_4+H_2O.$$

The yield obtained, however, was only 10 per cent. upon the nitrosamine.

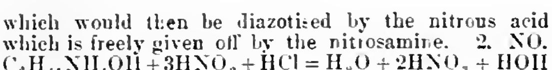
4. Experiments to produce nitrosoaniline by the action of boiling ammonia upon nitrosophenol proved fruitless, although under similar conditions nitroso-α-naphthol is converted into *α-nitroso-β-naphthylamine*—



$$C_{10}H_6\genfrac{}{}{0pt}{}{N}{NH}>O.$$

This the authors consider to be the proper constitution of Ilinski's naphthalene-α-oxime-β-imide (*Ber.* **17**, 391), obtained by the action of ammonia upon nitroso-α-naphthol, since this latter substance by treatment with ethylamine solution at 100° is converted into the same α-nitroso-β-ethylnaphthylamine, as described above. However, when one part of nitrosophenol, five parts of ammonium chloride, ten parts of dry ammonium acetate and a little ammonium carbonate, are mixed and heated together for half-an-hour upon the water bath, *nitrosoaniline* is obtained, which precipitates in the form of dark green crystals when the melt is thrown into cold water. Nitrosoaniline dissolves in water, forming a grass-green solution, which on boiling with NaOH, gives off ammonia, the soda salt of nitrosophenol being formed. It crystallises from benzene, forming beautiful steel-blue crooked needles, melting at 173—174°.

5. By the action of alcoholic HCl upon Schwebel's nitrosophenylglycin (*Ber.* **11**, 1132), a very interesting diazo compound is formed, most probably *diazo-phenylhydroxylamine*. One part of the nitrosamine is dissolved in two parts of absolute ether, and three parts of alcoholic HCl added. After twelve hours' standing, the bluish-red crystalline mass is filtered off, washed with ether, dissolved in cold alcohol, filtered and then precipitated by the addition of ether. The yellow leaflets thus obtained explode on heating, and are decomposed even by cold water, evolving two atoms of nitrogen. They dissolve without decomposition in concentrated HCl, and the platinum salt precipitates from this solution on the addition of $PtCl_4$, forming yellow leaflets, readily decomposed by water. The above reaction probably takes place in two stages, in the first of which *nitrosophenylhydroxylamine* would be formed:—



$$1.\ C_6H_4<\genfrac{}{}{0pt}{}{N.CH_2COOH}{NO}+H_2O=NO.C_6H_4.N<\genfrac{}{}{0pt}{}{H}{OH}$$

$$+C_2H_4O_2.$$

which would then be diazotised by the nitrous acid which is freely given off by the nitrosamine. 2. $NO.C_6H_4.NH.OH+3HNO_2+HCl=H_2O+2HNO_3+HOH$ $N.C_6H_4.N:N.Cl[N:N_2=1:4]$.—T. L. B.

Preparation of an Orange-red Colouring Matter. Z. Roussin. Bull. Soc. ind. de Rouen 1887, 45.

THE new colouring matter results from the action of naphthol on the azo-derivative of sulphanilic acid. An aqueous solution of an alkaline sulphanilate, mixed with a slight excess of a soluble nitrite, is decomposed in the cold by a dilute acid. A crystalline precipitate of the azo-derivative is formed; this is decomposed by boiling water and violently explodes when brought in contact with a flame. By treating, in the cold, the azo-derivative suspended in water with finely divided naphthol, with frequent stirring, the colouring matter separates after some hours without the evolution of gas. When the reaction is at an end, the mass is heated with boiling water, from which the colouring matter separates on cooling in brownish-red crystals, which can be easily washed with cold water. The colouring matter dyes wool and silk orange-red without mordants and from an acid bath. The colour is light-fast.—G. H. M.

On Azophenines and Indulines. O. Fischer and E. Hepp. Ber. **20**, 2479—2484.

THE authors dispute the correctness of the opinion expressed by Otto N. Witt (this Journal, 1887, 594), that the azophenines are simply oxidation products of aniline and not transformation products of the various amidoazo- or nitroso-compounds, by the help of which they are obtained. They hold that, as Kimich first stated, the nitroso-compounds themselves enter into the reaction, since they obtain with *p*-nitroso-diphenylamine and *p*-bromaniline a tetra-bromoazophenine, with *m*-hydroxynitrosodiphenylamine a hydroxyazophenine, and with monochloronitrosodiphenylamine a monochloroazophenine. Further, on heating dibromonitrosophenol with aniline and aniline salt, a brominated azophenine resulted.

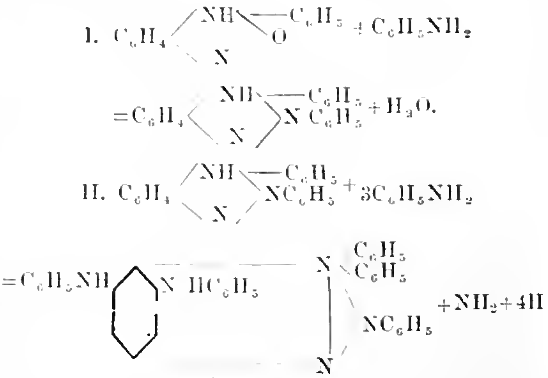
Azophenine $C_{36}H_{29}N_5$ can be produced in very many ways, besides those described by Witt and Kimich; it is easily obtained from nitroso-, mono-, methyl- or ethyl-aniline, but the best yield was obtained by heating 100 parts of *p*-nitrosodiphenylamine with 100 parts of aniline hydrochloride and 500 parts of aniline for eight to ten hours on the water bath. The yield of pure azophenine was 150 parts. As by-products were obtained a little induline, and *p*-amidodiphenylamine, melting at 66—67°. With *p*-toluidine, *p*-nitrosodiphenylamine yielded the same azotoline obtained by Kimich, melting at 249°.

Monochlorazophenine. $C_{36}H_{28}ClN_5$. The *p* chlorodiphenylamine was obtained, by Sandmeyer's method, from *p*-amidodiphenylamine; it melts at 74°, and yielded a nitrosamine, which was converted by the action of alcoholic HCl into *p*-nitroso-*p*-chlorodiphenylamine. From this substance the above azophenine was obtained; in appearance very similar to azophenine itself, but rather more soluble in benzene and toluene, and melting at 230°.

Tetra-bromo-azophenine. $C_{36}H_{25}Br_4N_5$. This substance is also very like azophenine; it melts at 243°, and is soluble in toluene or xylene. It was obtained by heating on the water bath one part of *p*-nitrosodiphenylamine with four parts of *p*-bromaniline and one part of *p*-bromaniline hydrochloride (or acetate).

Di-hydrazophenine, $C_{36}H_{31}N_5$, is obtained by heating azophenine with an alcoholic solution of ammonium sulphide under pressure to 130—140°. On cooling colourless glistening leaflets are obtained, sparingly soluble in alcohol, soluble in chloroform, and toluene. The solutions soon become red, azophenine being re-formed. It is soluble in HCl, and melts at 173—174°. When 1 part of azophenine is cohobated with 100 parts of alcohol, and 5 parts concentrated H_2SO_4 (60° B.), it gradually dissolves, forming a blue solution, from which small glittering needles settle out. These are insoluble in most solvents, crystallising from aniline in the form of silver-grey leaflets. The composition of this substance is $C_{24}H_{19}N_3O_2$, the azophenine being split up into aniline, and this substance, which contains two hydroxyl groups. $C_{36}H_{31}N_5 + H_2O = C_{24}H_{19}N_3O_2 + C_6H_5NH_2$. It dissolves in alcoholic caustic soda with a red-yellow coloration, in concentrated H_2SO_4 with a magenta coloration. Tin and HCl form a crystalline colourless reduction product. The alcoholic mother liquor from the above substance contains aniline and a small amount of a blue colouring matter.

From the above results the authors conclude that the reaction by which azophenine is obtained from nitroso-bodies may be expressed as follows:—$2C_{12}H_{10}N_2O + 4C_6H_5NH_2 = C_{36}H_{29}N_5 + 2H_2O + NH_3 + C_{12}H_{12}N_2$. Probably nitrosophenol or the nitroso-bases are first converted into *p*-nitrosodiphenylamine, owing to the ease with which they react with ammonia, anilines and amines in general (see preceding abstract). As *p*-nitrosodiphenylamine is doubtless a quinoneoxime derivative, it is probable that it will react with aniline as quinone does, which produces quinoneaniline, a substance resembling very much azophenine in its outward appearance, and therefore the reaction may be further expressed in this manner:—

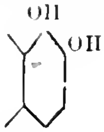


(azophenine).

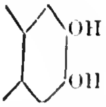
It is hoped that the above reactions will throw some light upon the constitution of the indulines, as *p*-nitrosodiphenylamine, when heated to 130—140° with 4 parts of aniline, and 1 to 2 parts of aniline salt, gives a good induline melt, containing much of the blue shade induline, and less of the red shade or azodiphenyl blue. Also azophenine when heated with equal parts of aniline and aniline salt, appears to be converted into the blue shade almost alone, it being still uncertain if any azodiphenyl blue is produced at the same time.
—T. L. B.

The Chromogenic Properties of the Oxyanthraquinones. C. Liebermann and St. v. Kostanecki. Annalen **240**, 245—304.

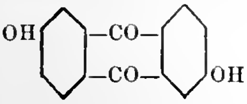
THE oxyanthraquinones may be divided into groups according to their colouring or non-colouring properties. The oxyanthraquinones, which give coloured lakes with alumina and oxide of iron, are very similar. Rufigallic acid and anthragallol form a different class of colouring matters, but possess similar shades among themselves. The mono-oxyanthraquinones possessing no chromogenic properties, yield, on fusing with potash, colouring matters formed by oxidation, in which process a second hydroxyl group is added. The colouring properties of these bodies depend upon the position of the hydroxyl group. That one hydroxyl is insufficient to produce chromogenic properties is seen from the fact that the two possible mono-oxy compounds are not colouring matters. Of the nine isomeric dioxyanthraquinones, only one, alizarin, is a colouring matter. The relative positions of the two hydroxyl groups is, therefore, an essential condition. Dioxyanthraquinones, with a hydroxyl in each benzene nucleus, may be regarded as mono-oxy compounds, and have no colouring properties. Quinizarin and xanthopurpurin have both hydroxyls in one nucleus, but possess no colouring properties. Of the four possible positions of the hydroxyls, the above two being excluded, there remain two, one of which is found in alizarin, to which the following formula has been given :—

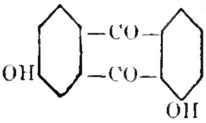


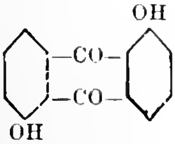
The second, with the formula—



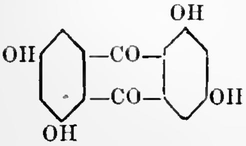
is not known. The difference of shade between alizarin and anthragallol is probably due to the second ortho-position of the third hydroxyl. That the colouring properties of these bodies is due to their acid nature, is shown by the fact that the acetyl- and methoxyl-derivatives are not chromogenic. And even the replacement of one hydrogen atom of the hydroxyl by an alcohol radicle destroys this property. This accounts also for the fact that the glucoside in freshly gathered madder root is a weak colouring matter. Of the six trioxy-compounds, two, purpurin and anthragallol, are colouring matters and have two of the hydroxyls in the same position as in alizarin; they are, therefore, mono-oxy alizarins. Purpurin is so closely related in shade to alizarin that the third hydroxyl appears to exert little influence of a chromogenic character. It is otherwise with anthragallol. Of the remaining four trioxy-compounds, one has been little studied, and the other three, flavopurpurin, anthrapurpurin, and oxychrysazin, have not had the positions of the hydroxyl groups definitely determined. It appears, however, that these are divided between the two nuclei. Both the mono-oxy anthraquinones, on fusion with potash, yield alizarin—*i.e.*, the adjacent hydrogen atom is in each case oxidised to hydroxyl. Anthraflavinic acid, benzdioxy-anthraquinone and anthrarufin, have one of the following formulæ :—



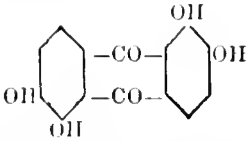




of which the last is probably that of anthrarufin. On fusion all these bodies take up oxygen, forming flavopurpurin, anthrapurpurin and oxyanthrarufin, which have much the same shade as alizarin. It is, therefore, not unlikely that the third hydroxyl takes up an adjacent position to one of the other two; and that the isolated group in the one nucleus has no influence on the chromogenic character of the body. It is a curious fact that when the alizarin hydroxyls are present, further oxidation, with the addition of more hydroxyl groups, ceases. That is to say, that no tetraoxyanthraquinones have been obtained by fusion from the trioxy-compounds. The greatest difference in properties is observed in the case of the six tetraoxyanthraquinones. Anthrachrysone, the constitution of which may be expressed by the following formula :—



has no colouring property. This is due to the absence of the alizarin hydroxyls. The constitution of rufiopin has not been completely cleared up; but, from its production from protocatechuic acid, has the following formula :—



and has chromogenic properties similar to alizarin. The two tetroxyanthraquinones, obtained from oxybenzoic acid and gallic acid, are oxyanthragallols and are colouring matters, with a shade similar to anthragallol. Finally, a new tetraoxy-compound quinalizarin has been obtained, and, from its formation, has two hydroxyls in the alizarin position in one nucleus, and two in the quinizarin, in the other. It produces a shade similar to alizarin, with a blue tinge. Of the isomeric penta- and hexa-oxyanthraquinones, only one of each has been prepared. The former, according to the manner of synthesis, is a dioxyanthragallol, and gives an anthragallol shade. Rufigallic acid, or hexaoxyanthraquinone, is a dianthragallol. From the above, it is seen that only those bodies which have the hydroxyls in the alizarin position yield colouring matters.—J. B. C.

The Manufacture of New Naphthol and Naphthylamine Monosulphonic Acids and of Dyestuffs therefrom. G. Pitt, Sutton. From Leopold Casella & Co., Frankfort-à-Maine, Germany. Eng. Pat. 12,908, Oct. 9, 1886. 6d.

THE new naphtholmonosulphonic acid (F) is prepared by fusing the α-naphthalenedisulphonic acid of Ebert and Merz (Ber. 9, 612), with alkali and stopping the fusion before both HSO_3 groups are replaced. In order to effect this, 10kilos. of the disulphonate of sodium are mixed with 40kilos. of 50% caustic soda and heated to 200° till traces of dioxynaphthalene begin to be formed (ascertained by acidulating a sample and extracting with ether, or by weighing the azo-compound formed with diazoxylene chloride). The melt is dissolved, acidulated, and boiled till free from sulphurous acid. The β-naphtholsulphonic acid F remains in solution, and can be used directly for the manufacture of azo-colours. The formation of dioxynaphthalene is best avoided by using only two molecules of caustic alkali to one of the disulphonate and heating for 16 hours in an autoclave to 250° C. The β-naphtholsulphonic acid thus formed is said to differ widely from all known isomerides: the aqueous solutions of the alkaline salts have a pure blue fluorescence; ferric chloride gives a dark blue colour in neutral solutions. The acid yields a nitroso-sulphonic acid by the action of nitrous acid and combines with all diazo-salts when these are made to act upon it in alkaline solution. The azo-colours thus formed are said to be bluer in shade than the corresponding compounds from Schaeffer's acid. The F sulphonic acid when heated with ammonia, gives a new β-naphthylamine-monosulphonic acid described in the specification as the F acid, the salts of which show a violet fluorescence. The F amidosulphonic acid can be readily diazotised, and then gives in combination with amines, phenols, and their sulphonic or carboxylic acids, a series of valuable dyestuffs. Conversely the amines or amidosulphonic acids may be diazotised and combined with the F amidosulphonicacid. As examples, the patentees mention the following azo-colours :—(1) The compounds produced by the action of diazotised aniline and its homologues, the naphthylamines, amidoazobenzene and its homologues, nitraniline and benzidine and their homologues, dianisidine and the sulphonic acids of all these bases, on the β-naphthol (F) monosulphonic acid in alkaline solution. (2) The action of the diazotised F-amidomonosulphonic acid on the foregoing amines and sulphonic acids, as well as on phenols and their sulphonic acids. (3) The action of the diazotised amines, etc., mentioned under (1) upon the F-amidosulphonic acid. Thus by the action of diazotised benzidine, etc., secondary azo-colours containing similar or dissimilar radicles (mixed tetrazo-colours) may be produced.

—R. M.

The Manufacture or Production of Colouring Compounds or Materials. C. A. Bennert, Blaydon-on-Tyne. Eng. Pat. 13,466, Oct 21, 1886. 6d.

THE colouring matters described are termed "thiamines" and are produced by the action of aromatic amines on sulphur dioxide. The following examples illustrate the process :—(1) Aniline sulphite is heated to 250° in a closed vessel for about 10 hours and the resulting mass purified by boiling with weak acid to remove by-products. Final purification may be effected by dissolving in cold strong sulphuric acid and pouring into water when the thiamine is precipitated and can be filtered off. (2) Aniline sulphite is mixed with one molecule of aniline and treated as in the last example. (3) Aniline sulphite is heated with two or more molecules of aniline as in the last example, and the excess of aniline blown off before purification. The addition of nitro-compounds, such as nitro-benzene, or of such compounds as azo, azoxy and hydrazobenzene, is said to increase the yield by diminishing the by-products. Examples of the use of these materials are given.—R. M.

Methods or Processes of Treating Oxynaphthol and Aniline or its Homologues, obtaining certain Products and utilising the same in the Manufacture of Dyes. J. Annaheim, Basel, Switzerland. Eng. Pat. 14,283, Nov. 5, 1886. 6d.

ACCORDING to this invention oxynaphthol is heated with or without condensing agents and a primary aromatic amine, such as aniline and its homologues, the naphthylamines, etc. Thus with aniline the following reactions take place :—

$$C_{10}H_6(OH)_2+C_6H_5NH =C_{10}H_6(OH).NH.C_6H_5+OH_2$$
$$C_{10}H_6(OH_2)+2C_6H_5.NH_2=C_{10}H_6(NH.C_6H_5)_2+2OH_2$$

In carrying out the process for the production of the second of these compounds (diphenylnaphthylenediamine) 16kilos. of oxynaphthol (Ebert and Merz, *Ber.* **9**, 609) are mixed with 37kilos. aniline and 13kilos. of dry aniline hydrochloride and the whole heated for several hours nearly up to the boiling point of the aniline. When purified the diphenylnaphthylenediamine is a white crystalline solid melting at 163·5° C. The corresponding compound from paratoluidine melts at 237° C. Two methods of obtaining dyes from these compounds are described :—(1) By heating the condensation product with a nitroso-compound, such as nitrosodimethylaniline hydrochloride "in conjunction with a suitable solvent." (2) By reducing the nitrosodimethylaniline to amidodimethylaniline and oxidising with potassium dichromate or ferric chloride in the presence of the condensation product. The characters of the colouring matters thus formed are not described.—R. M.

Manufacture and Treatment of a Compound of Phenyl Hydrazine with a new Ethylether. O. Imray, London. From the Society of Chemical Industry, Basle, Switzerland. Eng. Pat. 14,618, Nov. 11, 1886. 6d.

THE ethyl ether of a new acid, having the formula $C_{14}H_{24}N_2O_4$ (Eng. Pat. 14,617, 1886; this Journ. 1887, 653) is heated on the water-bath with phenyl hydrazine, when a violent reaction takes place and a yellowish crystalline mass separates. The ether may be first dissolved in boiling alcohol and then added to the phenyl hydrazine, in which case the new compound, which has the formula $C_{22}H_{28}N_6O_2$, separates on cooling either in crystals or as a crystalline powder. It melts with decomposition at 200°, is difficultly soluble in pure water or alcohol, slightly soluble in amyl alcohol and insoluble in methyl alcohol, acetic ether, chloroform, etc. Caustic potash or soda, sodium carbonate, mineral acids and acetic acid decompose it into methylhydroxyquinizine and ethylenediamine. When decomposed by heating to above 200° C. these products also result. Heated to 120—130° with methyl alcohol and methyl iodide for 12 hours the compound $C_{22}H_{28}N_6O_2$ yields antipyrine, which, after the removal of the volatile substances, is liberated by the addition of caustic soda and purified by extraction with alcohol or other suitable solvent.—C. A. K.

The Treatment of Certain Colouring Compounds or Materials for the Purpose of rendering them Soluble or more Soluble and Suitable for Dyeing and Printing. C. A. Bennert, Blaydon-on-Tyne. Eng. Pat. 13,473, Oct. 21, 1886. 6d.

THE object of this process is to convert the insoluble thiamines described in the last specification into sulphonic acids. This is effected by heating them with sulphuric acid or any appropriate sulphonating material. The details concerning the strength of acid, time, temperature, etc., are given in the specification. The thiamine-sulphonic acids are said to be colouring matters of various shades of blue suitable for dyeing and printing.

—R. M.

Improvements in the Preparation of Red Colouring Matters. J. H. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen-à-Rhine, Germany. Eng. Pat. 14,625, Nov. 11, 1886. 6d.

THESE are secondary azo-dyes possessing the property of dyeing cotton without the use of a mordant. The starting point in the manufacture of these compounds is α-naphthylene-diamine obtained by the reduction of β-dinitronaphthalene (m.p. 216° C.). The tetrazo-derivative of the diamine can only be formed in the presence of a large excess of acid, and this tetrazo-salt then combines with phenols, amines, and sulphonic acids in the usual manner. The present specification limits the claim to the compounds resulting from the action of one molecule of the tetrazo-salt upon two molecules of naphthionic acid or of the three mono-sulphonic acids of β naphthylamine. The diazotising is effected by mixing 23 parts of the finely-divided hydrochloride of the diamine in 125 parts of 35 per cent. hydrochloric acid mixed with 250 parts of water and an equal quantity of ice. The necessary quantity of sodium nitrite (14 parts) is dissolved in three times its weight of water and gradually added to the acid solution of the diamine, and when the action is complete the solution of the tetrazo-chloride is mixed with the necessary quantity of a solution of sodium naphthionate and sodium acetate. The colouring matter begins to separate at once, but the mixture must be kept agitated for several days in order to complete the reaction. The solution is finally made alkaline by sodium carbonate, boiled up and allowed to cool, when the sodium salt crystallises out. This colouring matter dyes vegetable fibre (from an alkaline bath) of a bright red shade, fast to light and moderate soaping, but becoming purple by the action of acetic acid, and dull green by strong hydrochloric acid. Isomeric compounds are obtained in a similar manner from the β-naphthylamine monosulphonic acids, the best results being given by (1) the acid obtained from Schaeffer's β-naphtholsulphonic acid ; (2) Dahl's acid obtained by sulphonating β-naphthylamine at 100° C., and (3) the δ-sulphonic acid obtained by sulphonating β-naphthylamine at a temperature above 150° C.—R. M.

The Manufacture or Production of Colouring Matters. C. A. Bennert, Hebburn-on-Tyne. Eng. Pat. 10,046, July 18, 1887. 4d.

THE colouring matters claimed in this specification are produced by the action of nitric acid on "thiamines" and their sulphonic acids. These nitrated products are termed respectively "thiamines" and "thiaminine-sulpho-acids," the latter being described as colouring matters of various shades of brown suitable for dyeing and printing. Details of the method of nitrating are illustrated by several examples in the specification.

—R. M.

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

Dyeing with Turkey-red. F. Storck and G. de Coninck. Bull. Soc. Ind. de Rouen, 1887, 44.

THE cotton goods are steeped in a bath of fatty acid neutralised with caustic alkali, then dried and exposed in the open air; the fat is removed by a passage through a solution of sodium carbonate and subsequent washing. The material is then steeped in aluminium acetate, aged, dunged, and dyed with artificiat alizarin. After dyeing it is dried and steamed for half-an-hour at a low pressure, whereby the shade changes from reddish brown to a powerful red. One or two washings with soap, with the addition of tin-salt, finally produces the finest Turkey-red colour. The superiority of this procedure amongst other things consists in the production of Turkey-red by means of a single oil-bath and in the employment of steam to brighten the shade. According to the observation of the authors, light is an important agent in the production of the fatty mordant. The latter is developed best in sunlight.—G. H. M.

Turkey-red Oil. F. Storck and G. de Coninck. Bull. Soc. Ind. de Rouen, 1887, 47.

THIS concerns the preparation of a fatty substance which gives very great brightness to alizarin-red. The substance can be applied both in the pressure dyeing and also in the colour-bath and therefore makes the passage of the material through a fatty preparation (oil-emulsion, sulpholeinic acid, etc.) unnecessary. The authors prepare the substance by the treatment of oil with sulphuric acid. The product obtained is submitted to the action of an oxidising agent (chloride of lime, potassium bichromate, etc.), again taken up with an acid and neutralised.—G. H. M.

The Whitening of Wool. H. Hofmann. Chem. Zeit. **11**, 1224.

UNLIKE cotton, wool cannot be bleached to a pure white; whatever bleaching agent is used the wool always retains a slight dull-yellow tint, which cannot be completely counteracted by the application of a blue dyestuff. In order to overcome this difficulty many attempts have been made to "dye" the wool white by the deposition in the fibre of a white pigment. One method consists in adding magnesium sulphate to a bath of carbonate of soda, in which the wool is steeped; on warming, magnesium carbonate is deposited in the fibre. This process has the objection that the magnesium carbonate, although at first tolerably adherent, after a time dusts off. Very good results are obtained by soaking the wool in a solution of cotton in ammoniacal-cupric-oxide, washing with water or dilute acid to precipitate the cellulose upon the fibre and finally treating with ether to render the film opaque and white. —A. G. G.

Improvements in Apparatus for the Preparation of Bleaching Solutions by Electrolysis. E. Hermite, Paris; E. J. Paterson and G. F. Cooper, London. Eng. Pat. 14,673, Nov. 12, 1886. 11d.

THE magnesium or calcium chloride, or other suitable solution, is submitted to the action of an electric current in a tank divided into two parts by a perforated partition; contained in the tank are the electrodes, preferably of zinc and platinum, and a screw propeller, which, by revolving, maintains a constant circulation of the solution. The electrodes are so placed relatively to the openings in the partition, that the solution in its circulation always comes in contact with these electrodes. The positive electrode is made up of thin plates of platinum cast into a suitable support at the top; by means of a mechanical device knives are kept constantly moving up and down over the surface of the zinc, to prevent any deposit accumulating thereon.—B. T.

Cleansing Compound for use in the Process of Bleaching Linen and Cotton Fabrics or Yarns, and other Cleansing Purposes. A. Hodgkinson, Ballyclare. Eng. Pat. 11,981, Sept. 21, 1886. 4d.

OIL of turpentine or resin is boiled with paraffin or petroleum oil, and then about an equal weight of (*a*) common soap or (*b*) soda or potash added. Compound (*a*) is for laundry use; compound (*b*) for addition to the chemicals used in the lime and soda boils of ordinary bleaching processes. The use in the mixture of carbonate or chloride of ammonium is claimed in the provisional but abandoned in the final specification. —W. E. K.

Improvements in Dyeing Cotton, Cotton Yarns, and Cotton Fabrics. F. A. Gatty, Accrington. Eng. Pat. 13,362, Oct. 22, 1886. 6d.

FOR dyeing yellow the cloth is padded in a solution of suitable strength of tribasic acetate of lead (obtained by mixing a solution of 30lbs. of acetate of lead with 1gall. of 25 per cent. ammonia), whereby the lead becomes fixed in the fibre without further treatment. The yellow is then produced by raising in bichrome in the usual way. If a green shade is required the cloth is dyed blue before treating with the lead salt.—W. E. K.

Improvements in Aniline Black Dyeing or Printing Processes for obtaining a Fast Aniline Black in Textile Fibres and Fabrics. A. Aykroyd, W. E. Aykroyd, and J. Smith, Bradford. Eng. Pat. 13,814, Oct. 28, 1886. 6d.

AS a preliminary to the usual dyeing or printing processes, the fibre or fabric is padded in sulphated oil or other oily or soapy emulsion, or is tinted with any suitable colouring matter, or these two preliminary treatments are combined.—W. E. K.

Improvements in Preparing Grey and Black Colouring Matters to be applied to Textile Fabrics and Materials. D. Stewart, Glasgow. Eng. Pat. 15,363, Nov. 25, 1886. 4d.

EARTHY COMPOUNDS of the class of diatomite, kieselguhr, etc., are carbonised in retorts and the grey or black product, finely ground, is mixed with albumen or other medium used by calico printers for the fixation of pigment colours.—W. E. K.

Improvements in Apparatus for Cleaning and Bleaching Cotton and other Fibrous and Textile Fabrics. W. P. Thompson, Liverpool. From J. Meikle, Providence, U.S.A. Eng. Pat. 9722, July 12, 1887. 8d.

IN place of the usual alkaline boiling in kiers, the cloth (several pieces at a time) is carried forward in the open width, in a crowded or folded form, on travelling tables, operated in the manner of endless bands. On these tables the cloth is subjected to a powerful spray of the hot alkaline liquor, whilst at the same time beaters or stampers play rapidly upon the fabric. Two or more of these tables, arranged one above the other, are contained in the tank in which the operation is carried on, and the surplus liquor is drawn off at the bottom. —W. E. K.

Improvements in the Manufacture and Application of the Compounds of Fluoride of Antimony, with the Chlorides or Sulphates of Sodium, Potassium or Ammonium. W. P. Thompson, Liverpool. From C. J. E. de Haën, List, Germany. Eng. Pat. 11,500, Aug. 23, 1887. 6d.

FLUORIDE of antimony ($SbFl_3$), which is obtained by dissolving pure antimonious oxide, free from iron, in aqueous hydrofluoric acid, yields crystalline double salts with solutions of the chlorides and sulphates of sodium, potassium and ammonium. These have the composition $SbFl_3.NaCl$, etc., and $SbFl_3.Na_2SO_4$, etc. The object of the production of these compounds is their use in dyeing and cloth-printing, in place of tartar emetic; they contain a higher percentage of antimonious oxide than tartar emetic. (The compound $SbFl_3.(NH_4)_2SO_4$ contains 46·94 per cent., tartar emetic 43·46 per cent.). The mode of applying these salts in dyeing is the same as in the case of tartar emetic, except that a smaller quantity is needed. The cost of these compounds per 100 parts of antimonious oxide contained, is considerably less than that of tartar emetic or of oxalate of antimony. Mixtures of the above chlorides and sulphates may be obtained, having a different composition from the original salts.—C. A. K.

VII.—ACIDS, ALKALIS AND SALTS.

Discovery of New Deposits of Phosphorite in Tunis. P. Thomas. Compt rend. 104, 1321.

In a former paper (this Journ. 1886, 169), the author drew attention to the occurrence of phosphorite deposits in Tunis. He has now made further explorations, with the result of discovering new deposits which may perhaps be employed for agricultural purposes.—G. H. M.

The Artificial Production of Manganese-blende. H. Baubigny. Compt. rend. 104, 1372.

A solution of manganese acetate gives with sulphuretted hydrogen in the cold, a copious precipitate of manganese sulphide, which in a sealed tube at 100°, more slowly at the ordinary temperature, becomes dense and crystalline. The author dissolved 1·1grms. of normal manganese sulphate in 150cc. of water, added a slight excess of ammonium acetate, a few drops of acetic acid saturated with sulphuretted hydrogen at 0° C. and sealed up the vessel. After five years' standing very fine octahedral crystals were formed, some of which were 0·4—0·5mm. long. The crystals exhibit the same crystalline form, colour, gravity, etc., as the natural manganese blend, MnS.—G. H. M.

Affinity of Certain Hydrated Sulphates of the Metals (Vitriols) for Sulphuric Acid. R. Fink. Ber. 20, 2106—2108.

The author digests the pure oxides of the metals (Cu, Zn, Mg, Fe, Co, Ni) with metallic sulphates, of the same and of other metals, in solution. In the first case the composition of the product is independent of the amount of the solution present, provided it is always of the same strength. The metallic sulphate gives up to the hydrated oxide both a portion of the salt and the metal, in the case of Cu and Zn. In the case of Co, only a very small portion is thus decomposed and the magnesium salt remains unchanged. The hydrates of Fe and Mn behave similarly to that of Mg. The hydrates of Co and Al could not be investigated, as they dissolve in their sulphates. Where mixed oxides and salts were employed, the following results were obtained:—

No.	Hydrate or Basic Salt.	Salt.	Amount of Metal in the Precipitate.
1	Zn	Cu	All the Cu
2	Cu	Fe	60·3 p c. Fe
3	Mg	Fe	71·2 " "
4	Co	Mn	11·7 " Mn
5	Ni	Mn	12·3 " "
6	Cu	Mg	No Mg
7	Mg	Ni	60·5 p.c. Ni
8	Fe	Mn	No Mn
9	Zn	Ni	Little Ni
10	Mg	Mn	71·2 Mn

—J. B. C.

Phosphoric Acid in Chili Saltpetre. C. Ochsenius, Jahrb. f. Min. 1887, 221.

Since the principal objection to the explanation of the formation of Chili saltpetre from guano, which comes in contact with the saline solutions of the nitrate beds, is based on the absence of phosphoric acid in the nitrate, the author sent for a series of strata from the nitrate beds of the pampa, eastward of Taltal, in the Chilian province of Atacama, and tested microchemically two beds above the ordinary sodium nitrate, pure white crystalline nitrate from the surface secretion of the latter, as well as the beds below the deposit. He detected phosphoric acid in both the beds above the nitrate deposit and in the ordinary sodium nitrate, the white crystalline nitrate and the beds below the deposit gave no reaction for phosphoric acid. The author also remarks that Streng has found phosphoric acid in borocalcite from Ascotan, in Bolivia, between Atacama and Tarapacá.—G. H. M.

The Action of Chlorine on Carbon Bisulphide, and of Sulphur on Carbon Perchloride. P. Klason. Ber. 20, 2376—2385.

Chlorine acts, as is well known, but little on carbon bisulphide at common temperatures, but in the presence of chlorine-carriers, such as iodine, the chlorides of antimony and molybdenum, etc. Chlorine quickly replaces the sulphur, forming ultimately carbon perchloride. If the action of chlorine be interrupted before the complete conversion of carbon bisulphide into perchloride has taken place, intermediate compounds, so-called carbon sulpho-chlorides, are formed. This is a distinct proof that the reaction proceeds in several successive stages. On the other hand, the whole process can be reversed by reconverting carbon perchloride into bisulphide. The author undertook the examination of all the details of these reactions. Dry chlorine was allowed to act on carbon bisulphide containing a trace of iodine and the process interrupted as soon as one molecule of carbon bisulphide had absorbed 5 atoms of chlorine. The product of the reaction turned out to be trichloromethylsulphochloride, $CCl_3.SCl$, a yellow oil having an extremely unpleasant and penetrating smell. This compound, in the pure state, absorbs chlorine in considerable quantities; but if the latter contains only a trace of iodine the chlorine is not merely absorbed, but substituted, thus:—$CCl_3.SCl + Cl = CCl_4 + SCl$. If sulphur in sufficient quantities is made to act on trichloromethylsulphochloride at 220° C., the products obtained are almost exclusively carbon bisulphide and perchloride. But if the same process be repeated at lower temperatures, many intermediate products are formed, such as carbon chloride, thiophosgene, perchloromethylbisulphide and perchloromethyltrisulphide. The primary products of the reaction are undoubtedly perchloromethylbisulphide and sulphur chloride, while the other compounds are probably products of decomposition of the latter two, thus:—$2CCl_3.SCl + S_2 = CCl_3.S_2.CCl_3 + S_2Cl_2$. By the action of silver dust on trichloromethylsulphochloride the same compound, perchloromethylbisulphide, was obtained. It forms a yellow, thick oil with a turpentine-like smell and undergoes decomposition on being distilled at the ordinary barometric pressure. One of the products of decomposition is thiophosgene, CCl_2S. Sulphur, heated with perchloromethylbisulphide at 170° C., formed a trisulphide, $CCl_3S_3CCl_3$, a thickish liquid which partially crystallises on the addition of water. If trichloromethylsulphochloride be reduced with tin and hydrochloric acid, thiophosgene is formed; the reaction proceeds so smoothly that it can be recommended for the preparation of this interesting compound. This phosgene, heated with sulphur at 130° to 150° C., formed chlorothiocarbonylsulphochloride, $CClS.SCl$, which is easily acted upon by chlorine, forming trichloromethylsulphochloride, thus:—

$$CClS.SCl + Cl = CCl_2S + SCl$$
$$CCl_2S + Cl_2 = CCl_3.SCl.$$

From these reactions the author concluded that the chlorination of carbon bisulphide passed through the following four stages:—

1. $CS_2 + Cl_2 = CClS.SCl$.
2. $CClS.SCl + Cl = CCl_2S + SCl$.
3. $CCl_2S + Cl_2 = CCl_3.SCl$.
4. $CCl_3.SCl + Cl = CCl_4 + SCl$.

If the process is reversed, sulphur being made to act on carbon perchloride, the reaction does not take place below 220° C. The final products are always carbon bisulphide and chloride, whereas, only rarely intermediate products can be obtained, which, however, were recognised in all cases as thiophosgene and trichloromethylsulphochloride. It is, therefore, highly probable that the series of reactions is as follows:—

1. $CCl_4 + S = CCl_3.SCl$.
2. $2CCl_3SCl + S_2 = C_2Cl_6S_2 + S_2Cl_2$.
3. $C_2Cl_6S_2 + S = C_2Cl_6S_3$.
4. $C_2Cl_6S_3 = CCl_3.SCl + CCl_2S + S$.
5. $CCl_2S + S = CClS.SCl$.
6. $CClS.SCl + S_2 = CS_2 + S_2Cl_2$.

The author is now engaged in examining the action of bromine on carbon bisulphide.—S. H.

Improvements in and Apparatus for the Treatment of Sulphate of Soda for the Manufacture of Sulphide of Sodium therefrom. F. H. Gossage, T. T. Mathieson and J. Hawliczek, Widnes. Eng. Pat. 12,480, Oct. 1, 1886. 6d.

Sodium sulphate is mixed with carbonaceous matter, and the mixture placed in a furnace containing coke at a red heat. The mixture fuses and passes down through the coke, whereby the reduction into sulphide is effected without the latter coming into contact with the lining of the furnace, which would be destroyed by the action of the fused sulphide. The furnace used has preferably the shape of a lime-kiln, and is furnished at the bottom with discharging doors. There are air openings about midway in the height of the furnace for admitting air for combustion of the coke; air is excluded from the lower part of the furnace, in which the reduction proper takes place. The coke, saturated with sodium sulphide, is then drawn off at the end of the operation, kept from the air until cool, lixiviated and the liquor used for the manufacture of pure soda products. The remaining coke may be used over again.—S. H.

Improvements in the Manufacture of Sulphuric Acid. J. B. Hannay, Loch Long. Eng. Pat. 12,247, Nov. 5, 1886. 4d.

Sulphurous acid from any available source is passed along with nitrous acid through a condensing tower, where the gases become minutely subdivided and thoroughly mixed by passing through screens, which are kept moistened by a continual stream of water trickling on them, with the result that the sulphurous acid is converted into sulphuric acid, which dissolves in the water. The process is continually repeated until the solution acquires considerable strength, when it is drawn off and a fresh supply of water is run into the apparatus. The uncondensed gases contain oxides of nitrogen, which are recovered by well-known means.—S. H.

Improvements in Apparatus for Use in the Treatment of Sulphuretted Hydrogen for the Separation of Sulphur, or for the Production of Sulphurous Acid. J. Simpson and E. H. Parnell, Liverpool. Eng. Pat. 14,711, Nov. 13, 1886. 8d.

In burning sulphuretted hydrogen, either for the preparation of sulphur or for the production of sulphurous acid of uniform strength, there is a great difficulty in regulating the respective currents of air and sulphuretted hydrogen entering the burner or combustion chamber: air in excess causing a loss of sulphur, while a deficiency of air allows the sulphuretted hydrogen to pass away undecomposed. The object of this invention is to regulate the supply of air and gas in any desired proportions, to measure the quantity of gas consumed and to minimise the risk of explosion by firing back. For this purpose two vessels are employed, each of which is provided with an inlet and an outlet valve. Both vessels are filled and emptied simultaneously by a mechanical arrangement, such as cylinders and pistons or gasholders raised and lowered in tanks containing liquid. The inlet valves of the vessels are connected respectively with the sulphuretted hydrogen storage tank and with the atmosphere, while the outlet valves are in connection with the burner or combustion chamber. The working parts of the mechanical contrivance are so coupled that the two vessels act in conjunction, and the air or gas entering and leaving one of the vessels in a given time has a constant proportion to the quantity of air or gas entering and leaving the other vessel during the same period.—S. H.

A Process for obtaining Mother-liquors free from Magnesian Salts in the Manufacture of Carbonate of Potash by Means of the Double Carbonate of Potash and Magnesia. E. P. Alexander, London. From E. J. L. Delsol, Lot, France. Eng. Pat. 15,182, Nov. 22, 1886. 6d.

In the manufacture of potassium carbonate by Engel's process, mother liquors are obtained, which, in addition to the untransformed salts of potash, contain magnesia salts. These salts are formed at the expense of a portion of the magnesia introduced in the manufacture, which has afterwards to be replaced and it would, therefore, be of great advantage to obtain mother liquors free from magnesia. For this purpose a quantity of sodium carbonate equivalent to the quantity of potassium carbonate which it is desired to obtain, is added. The sodium carbonate precipitates the magnesia, at the moment of its going into solution and at the termination of the operation the mother liquors contain no magnesia, but the corresponding sodium salt. The addition of sodium carbonate presents the further advantage, that instead of potassium chloride and magnesia, the double salt of potassium and magnesium chloride—*e.g.*, the raw salts of Stassfurt (carnallite, kainite, etc.), may be used with perfect success.—S. H.

Improvements in the Manufacture of Bi-carbonate and Carbonate of Soda by the Ammonia Process, and in the Construction and Use of Apparatus for that Purpose. H. Burns, Leith. Eng. Pat. 15,352, Nov. 25, 1886. 8d.

A boiler is filled with a solution of ammonium salts or with gas liquor and the temperature raised to about 270° F. Ammoniacal liquor is pumped constantly into the boiler so as to keep up a regular overflow of hot liquor from the top of the boiler into steam-tight cylinders, where the liquor mixes with a shower of milk of lime, which liberates the ammonia. The latter, along with a portion of the steam, is conducted into an elevated vessel containing ground rock salt, where the steam condenses, dissolving part of the salt, and runs down into a second vessel, called the mixing vessel. This vessel is filled with a saturated solution of sodium chloride and into it a constant stream of saturated brine is pumped, while the overflow is made to run down into a condenser and thence into the decomposer. At the same time the ammonia is passing through the salt solution a regular current of carbonic acid is also forced through it. Both the vessel containing the salt solution and the decomposer contain a frame of agitating balls with cups, through which the liquor and gases are forced. The agitation produced by the rising and falling of the balls causes an intimate contact of the different compounds, with the result that a precipitate of sodium bicarbonate settles at the bottom of the precipitating vessel, while the solution of ammonium chloride collects in the decomposer. This solution is pumped back into the boiler and re-enters the cycle of operations. When crude gas liquor is used, the gases and vapours must be purified before passing them through the salt solution. The bicarbonate, after being washed and dried, is packed into drums with perforated centre-tubes, which allow the gases to escape during the subsequent heating, and the drums are placed in retorts for the conversion of the bicarbonate into carbonate.

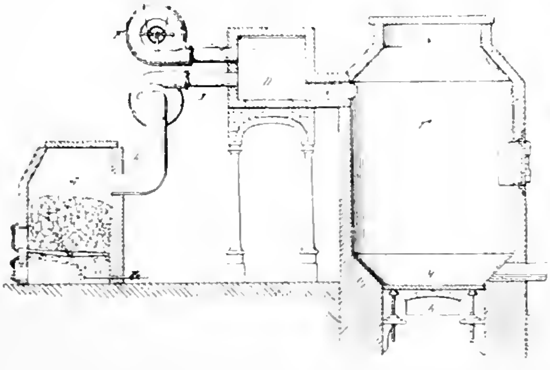
S. H.

An Improved Method or Process of Producing Muriatic Acid. H. H. Lake. From A. Kayser, H. Williams and A. B. Young, Buffalo, U.S.A. Eng. Pat. 11,494, August 23, 1887. 6d.

A SOLUTION of calcium chloride, such as is a waste product in various processes, is partly evaporated and mixed in this moist condition with silica or clay. The mixture is moulded with bricks, which after drying are placed into a converter heated to a very high temperature by gases which contain steam. At this high temperature the silica or clay decomposes the calcium chloride, forming calcium silicate or silico-calcium-aluminate and generating hydrochloric acid, which is condensed in any suitable manner. The product of the reaction left in the converter may be used for the manufacture of hydraulic lime and artificial stone. The use of clay is preferable to the use of silica alone, as the latter requires a higher temperature in the converter. The apparatus described in Eng. Pat. 11,492, 1887, is also suitable for this process.—S. H.

Improvements relating to the Production of Caustic Alkali, Carbonates of the Alkaline Metals, Muriatic Acid and other Substances. H. H. Lake, London From A. Kayser, H. Williams and A. B. Young, Buffalo, U.S.A. Eng. Pat. 11,492, Aug. 23, 1887. 8d.

CLAY, common salt and water are mixed together and the mixture moulded into bricks of convenient size. These are dried and heated in a converter by a current of hot gases superheated steam. The clay acts on the sodium chloride, generating hydrochloric acid long before visible red heat is reached, and the action increases rapidly as the temperature rises. The conversion is complete after about 24 hours' heating at a red heat. The hydrochloric acid is condensed in the usual manner. The converted material is termed "acid silico sodium aluminate." The clay and salt of the charge are mixed in such proportions that this aluminate contains about 33 per cent. of sodium oxide. It is then nearly insoluble in water and infusible even at the beginning of white heat. In order to extract sodium oxide from it, it is crushed and fused with such a quantity of soda as will raise the total percentage of soda to about 50 per cent. The resulting product, termed "basic silico sodium aluminate," is very deliquescent and yields all of its sodium compounds by lixiviation. The basic salt is, therefore, treated with water, when it yields a solution containing 80 to 90 per cent. of the total sodium as sodium hydrate, the rest being sodium carbonate and sodium silico-aluminate. The insoluble residue is regenerated clay, free from iron, and can be used over again in place of the original clay. As regards the composition of the clay, the best results are obtained when the proportion of silica to alumina is about two to one, and it is usually necessary to prepare a clay of suitable composition by adding or removing sand from it. The gases entering the converter should contain a sufficient quantity of steam to furnish hydrogen for combination with the chlorine and an excess of oxygen to prevent formation of carbon monoxide and the reducing action resulting therefrom. When it is desired to produce potassium salts, an equivalent quantity of potassium chloride should be used in place of sodium chloride. The accompanying drawing represents a section of the apparatus employed. A is the gas producer, and *a* a steam pipe supplying steam to the producer. The gas escapes at *b* and is drawn by a fan C into the combustion chamber D, while another fan E delivers a blast of air for burning the gas ; *f* connects the converter F with the combustion chamber. The converter is provided with a feed-opening G and a discharging door at H. The pipe I leads the escaping gases to the acid condensers. Two or more converters may be used in a battery; the gas exit pipe of one converter is then connected with the gas inlet of the following one.—S. H.



VIII.—GLASS, POTTERY AND EARTHENWARE.

An Improved Method or Process of Producing Silicate of Sodium or of Potassium. H. H. Lake. From A. Kayser, H. Williams and A. B. Young, Buffalo, U.S.A. Eng. Pat. 11,493, August 23, 1887. 8d.

FINELY-DIVIDED SILICA, sodium chloride and water are mixed and the mixture moulded into bricks. The quantity of sodium chloride should be so calculated that the resulting mass does not contain more than 15 per cent. of sodium oxide. The bricks are dried and placed into a converter of fire-brick heated by gases from a combustion chamber located near it. In this combustion chamber water-gas is burned by a blast of air in slight excess, forming carbon dioxide and steam under development of a high temperature. The hot gases pass through the converter and come in intimate contact with the charge, penetrating it thoroughly and causing at a bright red heat the gradual combination of silicic acid and soda, while hydrochloric acid is given off and condensed in the usual manner. When the operation is complete, the resulting mass forms an excellent material for the manufacture of glass in place of a portion of the soda and sand ordinarily employed; or by smelting the silicate with soda, water-glass is produced. The apparatus shown in the preceding abstract is also suitable for this process.—S. H.

X.—METALLURGY, Etc.

The Bending, Tensile and Compressive Strength of Samples of Magnesium.

THE following experiments were made for the Aluminium and Magnesium Manufactory in Bremen, at the Mechanical Experimental Station, in Charlottenburg. Tensile strength, limit of breaking, 23·2kilos. per 1qmm.; specific resistance to compression 27·2kilos. per 1qmm. ; bending strength 17·4kilos.

In comparison with other metals, the strength of magnesium is relatively very considerable. The breaking coefficient for tensile strain per square millimetre is :—

		Specific Gravity.
Magnesium	23·2kilos.	1·75
Aluminium	20·5 „	2·67
Brass	12·5 „	7·8–9·5
Bronze	23·0 „	8—9
Rod-iron	38·0 „	7·6—7·8
Delta-metal, poured in sand	31—36„	8·6
Delta-metal, rolled hard	53·0	—

Since the rolling of magnesium does not offer the slightest difficulty, even in such complicated forms as T I U, or as angles, round or four-cornered rods, plates or sheets of 0·1mm. thickness, and as pure magnesium is sufficiently resistant to atmospheric influences and can be polished and easily cleaned, it lends itself on account of its lightness and relative strength to the construction of apparatus, etc., required to be made of metal and also to be light—as for instance, nautical, physical and astronomical instruments. The working of magnesium requires heat. At a temperature of 450° C.

it can be rolled, pressed, worked and brought into complicated forms. Screws and threads can be made of magnesium and these are considerably sharper and more exact than those from aluminium. Owing to its cheapness, magnesium can also be used in the manufacture of a variety of useful articles; experiments in this direction are now being made.—G. H. M.

Examination of Zinc Muffles. Steger. Ztschr. f. d. Berg, Hütten- u. Salinenw. 1887, 165.

The author considers that most interesting and important results may be obtained from the study of the products remaining in zinc muffles after the distillation of zinc. The original mass may be converted into new and crystalline minerals; this would explain the formation of many crystalline minerals in volcanic rocks. The author has examined charges before and after distillation, and finds that considerable changes take place.

G. H. M.

On Germanium. C. Winkler. J. Prakt. Chem. **36**, 177—209.

In this communication (the second) on germanium, a more detailed description is given of the metal and of its compounds with the halogens, alcohol radicles, etc. Germanium is prepared from argyrodite by fusing it with equal weights of soda and sulphur. The melt is extracted with cold water, treated with an excess of sulphuric acid and the precipitate is filtered off and washed. After stirring up with water the precipitate is treated with sufficient hot caustic potash to dissolve all the soluble sulphides and the yellow alkaline liquid is separated by decantation from the insoluble sulphides of the heavy metals. Dilute sulphuric acid is added as long as it produces a precipitate and the solution containing the germanium and K_2SO_4 is filtered from the sulphides of antimony and arsenic; after adding an excess of H_2SO_4 it is evaporated down until acid fumes begin to escape. The acid mass is dissolved in water and saturated with H_2S, the precipitate filtered off, transferred to a porcelain dish, heated, moistened with HNO_3 and again heated to redness, so as to convert it into germanium oxide, which can be reduced in a current of hydrogen at a red heat. The oxide obtained as above is however impure and it is best to convert it into the insoluble potassium germanium fluoride by dissolving in hydrofluoric acid and adding potassium fluoride. This can be brought into solution by fusing with potassium carbonate and sulphur and extracting with water, when it is again treated as above. Large quantities of the oxide are best reduced to the metallic form by mixing with 10—15 per cent. of starch and hot water and heating with charcoal in a crucible. The semi-fused regulus is again melted under borax-glass, when the germanium is obtained as a partially crystalline mass.

Chlorides of Germanium.—Germanium forms with chlorine a dichloride ($GeCl_2$) and a tetrachloride ($GeCl_4$). The latter can be obtained by the direct union of its elements and also by heating a mixture of germanium sulphide and mercuric chloride, when cinnabar is left behind. The colourless fuming liquid obtained by heating powdered germanium in a current of dry HCl is not the dichloride, but germanium-chloroform, $GeHCl_3$, hydrogen being evolved during the process; the reaction which takes places is :—$Ge + 3HCl = GeHCl_3 + 2H$. The compound is very unstable, being readily oxidised with formation of an oxychloride ($GeHCl_3 + O = GeCl_2O + HCl$) and on heating it appears to decompose like silicon-chloroform according to the equation $2GeHCl_3 = Ge + GeCl_4 + 2HCl$. Victor Meyer and Mensching find that its vapour density is 5·55—the theoretical vapour density being 6·21.

Fluorides of Germanium.—Germanious fluoride, GeF_2, has not yet been prepared in a pure state, but it probably exists. The tetrafluoride (GeF_4, germanic fluoride) is formed when the oxide GeO_2 is dissolved in hydrofluoric acid; after evaporation over sulphuric acid it remains as a clear viscous liquid, which is very hygroscopic and gradually solidifies to a transparent mass having the composition $GeF_4 + 3H_2O$. This melts in its water of crystallisation when heated and on further heating becomes covered with a coating of oxide. Krüss and Nilson have recently stated that the fluoride is non-volatile. The author denies this and describes several experiments which support his views. In one of these, germanic oxide (or germanic acid, GeO_2) was gently heated with CaF_2 and H_2SO_4; penetrating acid fumes were evolved, which were readily absorbed by water, yielding a clear, colourless, acid liquid, which contained in solution hydrogen germanium fluoride H_2GeF_6 (corresponding to hydrofluosilicic acid). The potassium salt of this acid, K_2GeF_6, is prepared by dissolving GeO_2 in hydrofluoric acid and adding a concentrated solution of KCl; it forms a fine crystalline powder, similar in its properties to the fluosilicate of potassium. The existence of this salt confirms the anticipations of Mendelejeff, who predicted that Eka silicon would form double fluorides isomorphous with the corresponding salts of silicon, titanium, zirconium and tin.

Mendelejeff also stated that Eka-silicon, like Si and Sn (but unlike Ti, which belongs to an uneven series) could form volatile organic compounds such as $Es(C_2H_5)_4$, which should boil at 160° and have a density of about 0·96. This prediction has been completely verified. Germanium-ethyl, $Ge(C_2H_5)_4$, is formed by the action of zinc-ethyl upon germanic chloride :—$2Zn(C_2H_5)_2 + GeCl_4 = 2ZnCl_2 + Ge(C_2H_5)_4$. It is a colourless liquid of weak alliaceous odour, boiling at about 160°: it does not mix with water, but rises *slowly* to the surface when poured into water, thus showing that its density must be near 0·96. Its theoretical vapour-density is 6·51, but the value found by Victor Meyer and Mensching from a specimen which was shown by analysis to be pure, was 8·50.—D. E. J.

Improved Process for Extracting Gold and Antimony-Regulus from Auriferous Antimony Ore. E. R. Cummins, London. From G. P. Schweder, Porto, Portugal. Eng. Pat. 12,428, Sept. 30, 1886. 6d.

The crushed ore is roasted *per se* in a long reverberatory furnace at a gradually increasing, but always low, temperature, by continuously charging at the cooler end and working the charge up towards the fire bridge, where it is removed; it is then roasted absolutely sweet at a higher temperature and in a smaller furnace. Or it may be mixed with from 5 to 40 per cent. of lime, or of the carbonate or sulphate of magnesium, sodium or potassium, and subjected to similar treatment. Or these bodies may be mixed after the first calcination, but previous to treatment in the smaller furnace. After cooling, the gold is extracted by amalgamation or chlorination. The residue from this operation is dried and smelted for crude antimony regulus in a reverberatory furnace with powdered coal and a flux: or it is moulded into bricks with lime or clay and worked in a cupola.—W. G. M.

Improvements in the Manufacture of Aluminium Chloride and in the Extraction of Aluminium therefrom. O. M. Thowless, Newark, U.S.A. Eng. Pat. 14,407, Nov. 8, 1886. 6d.

Aluminium chloride, preferably produced by dissolving recently precipitated aluminium hydroxide in hydrochloric acid, or aluminium fluoride or other similar compound is mixed with chalk, coal or other carbonaceous material, sodium carbonate or soda ash, and cryolite. The mixture is then heated in a closed vessel at a temperature of 2000° F., cooled and washed to separate the reduced aluminium, which may then be remelted and run into ingots.—W. G. M.

An Improved Process and Apparatus for obtaining Sulphur and other Substances from Ores, for Purifying such Substances, and for similar Purposes. J. R. Francis, Swansea, and F. F. Jones, London. Eng. Pat. 14,875, Nov. 16, 1886. 8d.

The ore containing the sulphur or other volatile substance is roasted in muffles, the products of combustion being carried by a draught, induced by a flue stack, through a series of depositing chambers preceded, if desirable, by a reducing chamber packed with charcoal or a similar deoxidising substance. In these chambers, which are water-cooled, condensible products such as arsenic trioxide or sublimed sulphur are deposited; but the more volatile substances are carried on to the stack, in which they ascend over trays of limestone or magnesia and thus become absorbed. A gentle stream of water admitted at the top of the shaft dissolves such of these products as may be soluble and conveys them to a tank situated at the bottom. Two sets of condensing chambers may be used alternately, access to each being controllable by cocks in the main pipe from the muffle; the deoxidising chamber may be similarly thrown in or out of circuit at will. Thus pyrites may be treated first by distillation without access of air to the retort and the sublimed sulphur condensed in one set of chambers, when the roasting may be completed in presence of air, the products now being diverted into the other set; or ores containing two bodies which sublime at different temperatures, such as sulphur and arsenic, may be fractionated by respectively treating at the temperatures most suitable and collecting the products separately.—W. G. M.

Improvements in the Manufacture of Steel and Ingot Iron by the Basic Process. P. C. Gilchrist, London. Eng. Pat. 11,474, Aug. 23, 1887. 4d.

In the basic open-hearth process, instead of using an admixture of scrap, which requires a longer time to melt than does the accompanying pig iron, the furnace is charged in the usual way, but without the addition of the scrap and with a smaller proportion of lime than is theoretically necessary to purify the pig. Meanwhile, another portion of pig iron, preferably phosphoric, is blown with an excess of lime in a basic converter. When the charge in the open-hearth furnace is melted or is semi-fluid, that from the converter, together with its slag, is tapped in. The thoroughly liquid converter slag, containing, as it does, excess of lime, ensures a complete purification of the charge with greater rapidity than is usually possible, owing to the very gradual fluxing of the lime which ordinarily occurs; also the presence of oxides of iron in the same slag permits the use of a smaller quantity of ore during the process.—W. G. M.

XI.—FATS, OILS, AND SOAP MANUFACTURE.

On the Composition of Rape-seed Oil. C. L. Reimer and W. Hill. Ber. **20**, 2385—2390.

The rape-seed oil, in spite of its large consumption, is, from a chemical point of view, one of the least known fat oils. There exist only a few investigations of it and these are of old date and contradictory in their results. The authors have been engaged for some time in the investigation of erucic and brassic acids, and extending their work on the acids occurring in rape-seed oil, found that, contrary to previous statements, rape-seed oil contained three different acids, one of which fusing at 75°, was only present in very small quantities, whereas the other two, erucic acid and a liquid acid occurred in about equal quantities. The liquid acid mentioned and now termed "rapic acid," had been previously observed by Websky (*J. Prakt. Chem.* **58**, 449), but he did not study it much further, probably owing to the fact that he experienced great difficulties in separating it from the erucic acid. The usual means of separation by the different solubilities of their lead salts, failed in this instance; but it was found that of erucic and rapic acids, the zinc salt of the latter is easily soluble in ether, whereas that of the former is nearly insoluble in the same solvent. Zinc rapate forms a white crystalline mass, from which the free acid is obtained by heating with tartaric acid. On analysis the rapic acid was found to have the formula $C_{18}H_{34}O_3$. It is therefore an oxyoleic acid and although isomeric to ricinoleic acid, it differs in properties. It cannot be solidified by treatment with nitrous acid nor by cooling. Fused with potassium hydrate, it is decomposed with the evolution of hydrogen. The melt dissolved in water and acidified with hydrochloric acid, precipitates a white substance, which is a mixture of two crystallisable acids, which acids can be separated by a long-continued fractional crystallisation. The acid occurring in very small quantities along with the erucic and rapic acids, is obtained by saponifying 1kilo. of rape-seed oil and precipitating the solution with 4grms. of zinc acetate. The precipitate is filtered, washed and then decomposed with hydrochloric acid. The resulting product is purified by crystallisation from alcohol. It forms silver-shining plates and on analysis was found to have the formula $C_{22}H_{44}O_2$. It was identified as behenic acid. The rape-seed oil therefore contains the glycerides of erucic, rapic and behenic acids.—S. H.

XII.—PAINTS, PIGMENTS, VARNISHES AND RESINS.

Improvements in the Manufacture of Pigments. F. M. Lyte, Putney. Eng. Pat. 11,889, Sept. 18, 1886. 6d.

This invention is an improvement in the method of manufacturing basic salts of lead for use as pigments described in Eng. Pat. 10,298, 1886. A solution of basic lead acetate, prepared by repeatedly pouring neutral lead acetate over finely-divided lead, is treated with sulphuric acid till barely acid, heated to boiling and the precipitate allowed to settle. The clear liquid is decanted off and again rendered basic by pouring over finely-divided lead. To the precipitate of lead sulphate, a known volume of basic lead acetate, containing a given amount of base, is added and the mixture boiled for a short time, when "it will be found that the sulphate has attained its right degree of basicity."—O. H.

Improved Process of Manufacturing White Lead. J. F. F. F. Löwe, Frankfort, Germany. Eng. Pat. 9122, June 27, 1887. 4d.

The carbonate of lead is first prepared from solutions of lead nitrate or acetate by precipitating with bi-carbonate of soda or potash, or with a mixture of bicarbonate and carbonate. To the carbonate of lead thus prepared is added a solution of basic acetate of lead, when white lead settles down.—E. E. B.

New Process for the Vulcanisation of Pure Caoutchouc in Sheets or in Articles made therefrom. B. J. B. Mills, London. From A. Fayaud, Paris, France. Eng. Pat. 16,775, Dec. 21, 1886. 8d.

The caoutchouc is coated with sulphur, stoved and after being dipped in pure water, placed in a reservoir containing water and provided with a movable bottom. The reservoir containing the articles is then steamed in any suitable steaming apparatus under pressure. A drawing of the reservoir is given.—E. E. B.

Improvements in Indiarubber Compositions. J. T. Griffin, Hampstead. From R. J. Henderson, New York, U.S.A. Eng. Pat. 10,457, July 27, 1887. 4d.

Asbestos fibre, asbestos powder, ground whalebone, earth wax (paraffin, ozokerite, etc.), carbon (soot, lampblack, etc.) and sulphur are incorporated with Para or similar rubber before moulding and the mass is then cured in the ordinary way. The compound is said to be unaffected by the atmosphere, by acids and by oils.
—E. E. B.

Manufacture of Soft or Spongy Material from Rubber Compound. J. T. Griffin, Hampstead. From R. J. Henderson, New York, U.S.A. Eng. Pat. 10,458, July 27, 1887. 4d.

Substitutes for rubber sponge, termed by the patentee "light," "intermediate" and "heavy" sponge respectively, are made from Para rubber by incorporating with it sulphur, alum, tungstate of soda, borax, camphor, lampblack and either carbonate of ammonium for the "light sponge" or chloride of ammonium for the other two qualities. Proportions are given in the specification.

—E. E. B.

XIII.—TANNING, LEATHER, GLUE AND SIZE.

Improvements in Machines for Unhairing and Green-shaving Hides and Skins. J. W. Vaughn, Peabody, U.S.A. Eng. Pat. 10,121, July 19, 1887. 11d.

The hide to be operated on is clamped to a semi-cylindrical table with a rotary motion and brought in contact with a roll, the periphery of which is provided with metallic flanges arranged spirally, which revolves in an opposite direction to the table. For a description of the mechanism the specification must be consulted. Drawings are given, and there are 17 claims.

—B. H.

XIV.—AGRICULTURE, MANURES, Etc.

Analysis of Brewing Barleys of different Years. L. Aubry. Ztschr. f. d. ges. Brauw. 1887, 7.

The author publishes the analyses of barleys of the years 1878—1880, of which the following are the mean, maximum and minimum values :—

Barley of the 1878 harvest—66 barleys examined :—

In 100 parts of the dry substance.

	Water.	Nitrogen.	Albuminoids.	Ash.	Phosphoric Acid.	Starch.
Maximum	17·43	2·11	13·22	3·30	1·365	—
Minimum	12·55	1·21	7·60	2·42	0·715	—
Mean	—	1·73	10·81	2·98	1·020	—
Barley of the 1879 harvest—40 barleys :—						
Maximum	19·00	2·030	12·69	3·12	1·319	—
Minimum	12·00	1·0289	8·06	2·53	0·852	—
Mean	—	1·710	10·93	—	1·100	—
Barley of the 1880 harvest—76 barleys: —						
Maximum	20·70	2·400	15·00	—	1·696	68·65
Minimum	11·76	1·337	8·36	—	0·756	61·21
Mean	—	—	10·51	—	1·056	65·42

The ash of 15 of the above barleys was analysed :—

In 100 parts of the dry substance.

	Ash.	Iron Oxide.	Lime.	Magnesia.	Potash.	Phosphoric Acid.	Sulphuric Acid.
Maximum	3·1	0·043	0·093	0·286	1·032	1·203	0·216
Minimum	2·47	0·039	0·051	0·191	0·502	0·885	0·061

—G. H. M.

Effect of Noxious Vapours on Vegetation. E. Fricke. Landw. Versuchsst. 1887, 275.

In a neighbourhood suffering from the sulphurous smoke from a zinc (blende) smelting-works, grain crops grew thin, the ears were small and the stalks weak; whilst potato leaves were wrinkled and marked with black spots. These sickly plants contained more sulphuric acid than healthy plants grown in the same neighbourhood, but at a greater distance from the works. The excess of sulphuric acid varied from 0·442 to 4·5grms. per 1000 of dry matter. Taking these quantities as representing the injurious amount of sulphuric acid in each case, the author's results support the suggestion of Schröder and Reuss, that with regard to sulphurous smoke, young meadow herbage is most susceptible, oats can resist its injurious action better than wheat, while potatoes, on the other hand, can thrive within the limits of smelting works. Leaves and needles from trees exposed to such smoke, yield ashes containing more sulphuric acid, but less carbonic acid, and of lower basicity than ashes from healthy leaves and needles. With improved furnaces and means of removing the sulphur from smoke, such as are now known, this nuisance ought to be removed. Other experiments with plants grown in the vicinity of chemical works and exposed to smoke containing both hydrochloric and sulphurous acids, show that in the case of sickly plants the ash contains more hydrochloric and sulphuric acids, less carbonic acid and lower basicity than ash from healthy plants.—D. A. L.

Assimilation and Respiration of Carbonic Anhydride by Plants. U. Kreusler. Landw. Jahrb. 1887, 711.

Temperature plays an important part in both respiration and assimilation, in fact in the former case is of primary importance. Both respiration and assimilation take place within wide ranges of temperature, but the curve representing the relation of respiration to temperature takes a very different course to the corresponding curve for assimilation. Respiration becomes more intense with elevation of temperature and is at its highest at a point not far removed from the fatal temperature; this increase in intensity is not merely proportional to the rise in temperature, but goes on at a continually increasing progression. The author's experiments confirm the assumption that, under otherwise similar conditions, plants respire more carbonic anhydride at those periods of growth when the greatest changes in form and composition are taking place; for instance, during flowering and fruition. Changes in other conditions produce comparatively little effect on the intensity of respiration. With regard to the assimilation of carbonic anhydride by plants, the amount of water in a plant and consequently the water supply also, are the most important controlling factors and hence must be taken into consideration in all measurements, etc. Shoots of different stages of devolopment show visible differences in their energy of assimilation. At a temperation of 25°, an undoubted falling off in activity of assimilation is observed with advancing age of leaves. Older leaves contain less water and probably accumulate less than younger leaves; the difference between this power of accumulating water appears to be relatively greater than the difference between the evaporating power of old and young leaves. Under otherwise favourable conditions, raising the temperature to 25° does not necessarily produce an equal change in the amount of water in comparatively young leaves. Electric light, as supposed, proved as efficient as ordinary daylight in promoting assimilation in cut shoots during the more favourable periods of vegetation.—D. A. L.

Influence of Lime as a Soil Constituent on Vegetation. E. W. Hilgard. Forschungen auf. d. Geb. d. Agriculturph. 1887, 185.

Inasmuch as a high percentage of lime in soil induces short, strong and compact growth with high yielding power, of most trees and plants, whilst absence of lime, in spite of the otherwise good composition of a soil, produces weak growth and low yielding power: the author considers that the stunted round form of trees grown in arid districts may, at least to a great extent, be attributed to the same influence.—D. A. L.

Effect of removing Leaves from the Beet-root Plant on the Amount and Composition of the Produce. J. Fittbogen and R. Schiller. Chem. Zeit. **11**, 239—240.

The removal of leaves appears to interfere with the ripening of the plant, and early removal diminishes the total yield of nutritive organic substances.—D. A. L.

XV.—SUGAR, GUMS, STARCHES, Etc.

Study of the Products of the Saccharification of Starch. J. Effront. Monit. Scient. 1887, 513.

The author draws the following conclusions from his investigations:—(1) The course of the conversion of starch into sugar and dextrin is not the same whether the saccharification is effected by malt or acid. The saccharification by malt is attended by a decomposition of the starch molecule into dextrin and maltose, whilst the saccharification by acid is characterised by the conversion of the starch into dextrin and the latter into sugar. (2) The dextrins formed by the conversion of starch by the two agents named are not identical. The dextrins formed by the action of malt are polymeric, whilst those formed by the action of acid are not. (3) All these dextrins have the same rotatory power. (4) Maltose is always formed in the saccharification of starch by means of acid. The quantity increases as the saccharification proceeds. Even in the earlier stages of the saccharification there exists an almost constant ratio between the amount of glucose and maltose formed. This is 34—38 of maltose to 100 of glucose. (5) In the saccharification of starch by malt the formation of glucose is not regular. Whilst it almost always occurs in solutions of high gravity, it is only formed in liquids of low gravity if the malt extract employed be turbid. (6) The dextrin can be obtained pure, when the sugar is destroyed by a lactic acid fermentation. (7) For the analysis of the products of saccharification, the author proposes to destroy the sugars by means of ammonium hydroxide and sodium hypochlorite, and determine the dextrin by the polariscope readings of the solution before and after treatment.—G. H. M.

XVI.—BREWING, WINES AND SPIRITS.

Fifth General Meeting and Exhibition of the Berlin Brewery Institute. Chem. Zeit. **11**, 651—652.

The papers read at the above annual meeting were :—

1. *Hops and their Constituents, by Hayduck.*—The author has separated a new resin from hops. When hops are extracted with ether and the ethereal extract submitted to examination, three distinct resins may be separated ; one of these, a soft resin, is precipitated from its alcoholic solution by lead acetate and possesses remarkable antiseptic power ; the second, also a soft resin, is not precipitable by lead acetate, but it is soluble in petroleum ether and appears to be identical with the oxidation product of Bungener's acid from hops (this Journal, 1885, 543) and may be obtained from lupulin ; it possesses a much feebler antiseptic action than the former ; the third, which is a hard resin, is insoluble in petroleum ether, has only very slight antiseptic power, a less intense bitter taste and a pleasant smell. Both of the soft resins give a yellow coloration when treated with magnesium oxide in alcoholic solution ; under the same conditions the solid resin gives an orange-coloured precipitate. All the resins, when shaken in ethereal solution with copper sulphate solution, give a beautiful grass-green colour to the ethereal liquid. All the resins are soluble in water to the extent of about 0·042—0·058 per cent. The antiseptic action of the soft resins is very considerable on the lactic acid ferment, but it is very slight on sarcina and the acetic acid ferment. The solubility of the resin in water decreases on boiling (therefore the repeated use of hops is not to be recommended) and the presence of lactic acid in wort also reduces the solubility. This fact accounts for the formation of a film of resin on fermenting worts, since traces of lactic acid are always present in beer-wort.

2. *The Consumption of Fuel in Breweries, by Goslich.*—The author referred to the waste of heat in copper boiling and recommended boiling by steam, a discussion following on the relative merits of direct firing and steam boiling.

3. *The Influence of Carbonic Acid on the Fermentation and Keeping Properties of Beer, by Delbrück.*—Pressure of carbonic acid prolongs the fermentation and also checks the yeast-turbidity in the finished beer. The author, in conjunction with Foth, allowed beer to remain in bottle under a pressure of 2—4 atmospheres of carbonic acid and compared the results with those of beer bottled under ordinary conditions. The results were in favour of that bottled under pressure, the beer remaining bright for a much longer time. Pressure of carbonic acid does not check the growth of bacteria or sarcina. Enzinger considered that the prolonged influence of carbonic acid on beer improved it. V. de Planitz considered that air-pressure is preferable to carbonic acid pressure during the pasteurisation of beer.

4. *The Yield of Mashing Materials, by O. Reinke.*—The author determines the extract of a malt by analysing the malt and, after the mashing process is over, the grains, instead of by the usual methods of examining the wort. Under the most favourable conditions the yield of extract is equal to the theoretical, but various factors usually cause a loss of less than 12 per cent. of the theoretical yield. Normal grains contain on the absolute dry substance about 8 per cent. of extract, yielding 26 per cent. of starch and 45 per cent. of substances free from nitrogen. The high value of grains as fodder must therefore depend greatly on the easy digestibility and solubility of the altered cellulose of the malt, quite apart from the high percentage of proteïns.—G. H. M.

XVIII.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Obtaining Zinc in a Metallic Form from Alkaline Solutions of Zinc Oxide. W. S. Squire and S. C. C. Currie, London. Eng. Pat. 12,249, Sept. 27, 1886. 4d.

The solution is electrolysed with an anode of iron or carbon and a cathode of mercury. The resulting zinc amalgam is distilled to separate the mercury.

—W. G. M.

Obtaining Metallic Zinc from its Ores. W. S. Squire and S. C. C. Currie, London. Eng. Pat. 12,[illegible]0. Oct. 5, 1886. 4d.

The ore is dressed, obtained as oxide, if not already in this form, by roasting, dissolved in potassium or sodium hydroxide and electrolysed with a mercury cathode. The zinc is obtained by the subsequent distillation of the amalgam. (See Eng. Pat. 12,249 of 1886.)—W. G. M.

An Improvement in Electrolysis. C. D. Abel, London. From Messrs. Siemens and Halske, Berlin, Germany. Eng. Pat. 14,033, Nov. 1, 1886. 8d.

A solution of copper sulphate and ferrous sulphate with sulphuric acid, enters at the cathode (near the bottom of the cell) on which its copper is deposited by the electric current. It then passes over a non-metallic partition and falls along the surface of an insoluble carbon anode, the ferrous sulphate being meantime converted into ferric sulphate and acting, therefore, as a depolariser. This solution then flows from the cell over roasted copper pyrites, acting on the cuprous sulphide and copper oxide to form sulphate of copper, but not touching the iron oxide. In this process the ferric sulphate is again reduced to ferrous sulphate and the solution, thus brought to the same condition as before, passed again through the cells. Similar processes may be used employing zinc and other metals. If chlorides of the metals are used, ferrous sulphate is replaced by iron protochloride. The patent also relates to arranging several such cells in series. By these methods a lower counter E.M.F. is produced and the current is not wasted in reducing iron salts ; the anode also remains untouched.

—E. T.

Improvements in Apparatus for the Preparation of Bleaching Solutions by Electrolysis. E. Hermite, Paris, E. J. Paterson and G. F. Cooper, London. Eng. Pat. 14,673, Nov. 12, 1886. 11d.

See under VI., page 727.

Improvements in Holders or Supports for Incandescent Electric Lamps. J. H. Holmes, Newcastle-on-Tyne. Eng. Pat. 15,094, Nov. 20, 1886. 8d.

To obtain an even distribution of pressure between both of the platinum loops of electric lamps and the hooks of the holder, a spring is caused to act on the part of the lamp midway between the loops.—B. T.

Improvements in the Manufacture of Incandescent Electric Lamps. W. Maxwell, London. Eng. Pat. 15,165, Nov. 22, 1886. 8d.

WHEN the filaments have been attached to the connecting wires in the usual manner, they are placed upon a refractory conductor contained in an air-tight case, from which the air has been exhausted, and the conductor is electrically heated until carbonisation of the mount is complete. Sealing the glass stem of the bulb is accomplished by a similarly heated adjacent conductor. The bulbs are sometimes filled with nitrogen or hydrogen, which gases are maintained at any desired pressure or temperature in order to facilitate their purification. The gas-holder is connected with the lamps by inverted syphon tubes, preferably of steel, in which the mercury acts as a seal against admission of air. The mercury of the exhausting apparatus passes through a refrigerating chamber and the parts of the apparatus are connected together by inverted syphons as above.—B. T.

Improvements in Apparatus for Amalgamating Gold and other Precious Metals. B. C. Molloy, London. Eng. Pat. 15,206, Nov. 22, 1886. 11d.

WITHIN a shallow circular tray and floating freely upon the mercury contained in it, is a disc with sides higher than those of the outer tray, with a central aperture carrying a hopper for the introduction of the ore, and a cross-bar through which passes a spindle required for the rotation of the disc. Attached to the spindle and to the circumference of the disc are wires dipping into the mercury for the purpose of preventing the aggregation of ore at any point. The spindle runs in a socket on the floor of the tray, and is supported by a cross-head above; it is rotated at about 10 revolutions per minute. The finely-crushed ore is fed in suitable quantities into the hopper, either dry or as pulp. It thence gradually finds its way spirally over the mercury in the bath, being impelled forward by the motion of the disc and the resulting centrifugal wave, until on reaching the circumference it deposits any mercury particles caught in it and overflows into such receptacle as may be provided to receive it. Thus each particle will remain in contact with the mercury for the space of about 15 seconds. If desired, a porous diaphragm may be provided, having a lead, carbon or other anode packed in sand, wetted with soda or dilute sulphuric acid, or any suitable electrolyte, beneath it; the mercury itself acts as cathode to a weak current of electricity and is thus preserved from "sickening."—W. G. M.

Improvements in Electrical Batteries, and in the Manufacture of Depolarising Bodies to be used therein. E. Barbier and M. Leclanché, Paris, France. Eng. Pat. 16,823, Dec. 22, 1886. 8d.

IN agglomerated depolarisers the agglomerating substance is usually a non-conductor of electricity, such as gum-lac. The inventors use a combination of a peroxide, such as peroxide of lead, manganese, etc., with graphite, pitch, sulphur and water. These are intimately mixed and compressed cold. The block obtained is heated slowly to about 350° C. The water and volatile oils of the pitch are driven off and, finally, the sulphur acting on the remnant of the pitch converts it into an unalterable conductor of electricity. The inventors also claim a sealed form of battery, containing a centre cylinder of zinc surrounded by a cylinder agglomerated as described.—E. T.

An Improved Insulating Material especially adapted for Covering Electrical Conductors. R. W. Eddison, Leeds. From J. Tatham, Philadelphia, U.S.A. Eng. Pat. 10,092, July 19, 1887. 4d.

THE claims are for an insulating material made of resin and cottonseed oil (to render the former tough), to which other materials may be added. Four to six parts of resin to one of the oil make a good mixture, but other proportions may be used.—E. E. B.

New and Improved Process and Apparatus for Procuring Aluminium. W. P. Thompson, Liverpool. From M. G. Farmer, Eliot, U.S.A. Eng. Pat. 10,815, Aug. 6, 1887. 8d.

AN aluminous material is either made into a paste with a suitable quantity of carbon, by means of molasses or other similar body, and moulded into rods of convenient size (¾in. in diameter by 2ft. long), or it is packed within a carbon tube by itself or mixed with a reducing substance. At one end of each rod is a projecting portion, which for convenience of connection will fit into a corresponding socket at the reverse end of any other rod. These rods are then so passed through the opposite side walls of a furnace, constructed of refractory material, that they meet in the centre. Beneath this point is an aperture communicating with a crucible beneath; above it is a similar vent for the discharge of waste gases into the air, whilst at the side, midway between the rods, is an opening for the admission of a jet of gas or of petroleum spray injected by steam or air, the combustion of which will cause a flame to play continuously on the points of the compound carbons. An electric arc is then formed between these two poles, with the result that as they are consumed the aluminium is reduced and falls in molten drops into the crucible. A suitable arrangement of shunt, solenoid and motor maintains the points at the right distance apart and gives the necessary feed to the rods. Several furnaces may be arranged in series and the current may be continuous or alternating.—W. G. M.

Improvements relating to the Conversion of Chemical Energy into Electrical Energy, and to Apparatus therefor. H. H. Lake, London. From W. E. Case, New York, U.S.A. Eng. Pat. 11,188, Aug. 16, 1887. 8d.

THE soluble element is either free carbon, or a compound reducible to free carbon which must be a conductor of electricity. The solution contains oxygen in unstable equilibrium and is preferably peroxide of chlorine. An anode such as platinum is used. The cell is charged with peroxide of chlorine by pouring in first sulphuric acid and then adding chlorate of potash.—E. T.

XIX.—PAPER, PASTEBOARD, Etc.

Improvements Relating to the Treatment of the Spent Lyes used in the Manufacture of Cellulose by means of Sulphites, for the Recovery of Sulphurous Acid therefrom, and to the Utilisation of the said Lyes after such Treatment. A. Frank, Charlottenburg, Prussia. Eng. Pat. 13,286, Oct. 18, 1886. 6d.

THE lyes resulting from the manufacture of cellulose, paper pulp, textile fibres, etc., by the sulphite process contain sulphurous acid, some of which is free, while some is in the form of sulphites and bisulphites. The present invention relates to the removal and recovery of the sulphites from the lyes, so that the remaining solution can be utilised for forage and manuring purposes. When the lyes contain lime or magnesia as a base, a quantity of caustic lime is added equivalent to the proportion of sulphurous acid present. When the lyes contain the sulphite or bisulphite of soda or potash, a mixture of calcium chloride and lime is added, so that the amount of calcium chloride is equivalent to the alkali, while the lime is in proportion to the sulphurous acid present. In every case the sulphurous acid is precipitated as calcium monosulphite, which is separated from the lyes by filter-presses. The organic matter still adhering to this precipitate is removed by elutriation with water, to which neutral salts (sodium or calcium chloride) can be added to increase the specific gravity. The calcium monosulphite, owing to its greater specific weight, thereby separates from the lighter organic substances. Or the purification may be effected by washing the precipitate with a highly-diluted solution of sulphurous acid or with a solution of calcium bisulphite, in either of which solutions the organic substances are soluble.

The purified calcium monosulphite is worked up for producing fresh solutions of bisulphites by either of the following processes:—(1) It is stirred up in an aqueous solution of sulphurous acid or (2) the monosulphite is treated with sufficient dilute sulphuric acid to combine with a part of the lime, the lime forming calcium sulphate (annalin, pearl hardening), whilst the sulphurous acid, which has thus become free, changes the undecomposed monosulphite into a solution of bisulphite of the desired composition; or (3) the monosulphite is introduced into a solution of sodium bisulphate, whereby a precipitate of calcium sulphate and a solution of sodium bisulphite is obtained. Owing to the use of caustic lime for the precipitation of the monosulphite from the lyes, these solutions will have an alkaline reaction, which makes them unfit for use as forage and manure. It is, therefore, of advantage to pass carbonic acid and air through the solution to precipitate the caustic lime and oxidise the last traces of sulphite still dissolved. If the use as manure be intended, a quantity of acid phosphate of lime is added sufficient for forming a basic phosphate with the caustic lime present.—S. H.

Improvements in Means or Apparatus for use in effecting the Recovery of Chemicals from Spent Liquors of Pulp Digesters. J. E. Warren and F. A. Cloudman, Maine, U.S.A. Eng. Pat. 11,610, Aug. 26, 1887. 8d.

THIS invention relates to an apparatus for recovering chemicals from the spent liquors of pulp digesters. The apparatus consists of an evaporating chamber, a combustion furnace and a rotary calcining furnace between the evaporator and combustion furnace The evaporator is provided with a series of screw conveyors placed near the hearth of the chamber, by means of which the liquid, which is in a syrupy condition, may be fed towards the inlet of the rotary calcining furnace. The latter is furnished with an agitator for detaching the chemicals from the sides of the furnace. The combustion furnace, near the outlet of the calcining furnace, is provided with a hollow throat, through which the spent liquor circulates before entering the evaporator. By this arrangement the throat is always kept cool and can be made of iron, which is the most desirable material. The throat projects into the outlet of the rotary furnace.

—S. H.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Sparteine. F. Ahrens. Ber. **20**, 2218—2222.

SPARTEINE is reducible with Sn and HCl, yielding a tin double salt, from which the base can be separated. The latter forms a nitroso-compound, which is decomposed with HCl and on distilling with potash in steam an oil passes into the receiver. This gives a platinum double salt of the formula $C_{15}H_{28}N_2(HCl)_2.PtCl_4$. On oxidising sparteine with $KMnO_4$ in an acid solution, formic acid is formed but no acid of the pyridine series. Sparteine dissolves in H_2O_2 and a violent reaction occurs with the formation of a white precipitate. This is filtered, the filtrate neutralised with H_2SO_4 and evaporated. To get rid of H_2SO_4, barium hydrate is added and excess of the latter subsequently precipitated with CO_2. On evaporation, an alkaline syrup remains which gives a double platinum salt of the formula $C_{15}H_{26}N_2O_2 2HCl.PtCl_4$.—J. B. C.

Addition Products of the Cinchona Alkaloids. W. J. Comstock and W. Koenigs. Ber. **20**, 2510—2527.

CINCHONINE $C_{19}H_{22}N.O$ and cinchene $C_{19}H_{22}N_2$ yield with bromine, cinchoninedibromide and cinchenedibromide. These split off HBr on treating with KOH, and give dehydrocinchonine $C_{19}H_{20}N_2O$ and dehydrocinchene $C_{19}H_{18}N_2$. In brominating cinchene two dibromides α and β are formed. Chinene also forms a dibromide $C_{20}H_{22}Br_2N_2O$ and by elimination of HBr yields dehydrochinene $C_{20}H_{20}N_2O$. Quinine, cinchonine, cinchene and dehydrocinchonine absorb the hydracids at −17° and form compounds analogous to the dibromo-compounds enumerated above. Quinine yields hydrochlorquinine; cinchonine, hydrochlorcinchonine, etc. The dibromides are obtained by acting upon the alkaloid with bromine in $CHCl_3$ solution. Cinchenedibromide may be distinguished from the β-compound as it crystallises with one molecule water. Dehydrochinene, obtained by boiling dry chinenedibromide with alcoholic potash, is a colourless crystalline body almost insoluble in water. Hydrochlorquinine $C_{20}H_{25}ClN_2O_2$, obtained by leaving the hydrochloride of the alkaloid in contact with an aqueous solution of HCl, saturated at −17°, for several weeks, is a crystalline substance. By the action of potash quinine is regenerated. The hydrobromide has the formula $C_{20}H_{25}BrN_2O_2.2HBr$ and dissolves completely in dilute KOH solution with a yellow colour. CO_2 precipitates the bromide again from this solution. It appears that by the action of HBr at a higher temperature, not only is an addition product formed, but the methoxy-group is also split off Cinchonine also takes up 1 molecule of HCl and HBr, forming hydrochlorcinchonine and hydrobromcinchonine.

When hydrobromcinchonine is boiled with alcoholic potash for 12 hours a considerable quantity of cinchonine is regenerated. In addition to this a second product remains in the ethereal mother-liquors from the cinchonine and has the formula $C_{19}H_{22}N_2O$. The authors give to this body the name isocinchonine. Hydrobromcinchene is a crystalline compound. Dehydrocinchonine absorbs concentrated HBr in the cold with the formation of hydrobromdehydrocinchonine. Neither the pyridine and quinoline bases nor the tetra- or hexahydrides of these absorb the hydracids at the ordinary temperature. Experiments with Fischer's base obtained by heating methylketol and methyliodide gave the same result, and the same with methyllepidone. The different action of the natural and the artificial bases therefore points to a difference in constitution, and it is little likely that the quinoline nucleus in the former compounds are hydrogenated either in the benzene or pyridine nucleus. As, moreover, cinchonine gives a nearly theoretical yield of cinchonic acid (Py-3-quinoline carboxylic acid), cinchonine probably contains the non-saturated group $C_{10}H_{16}NO$, in addition to the quinoline nucleus with which the hydracids form addition products. This group contains probably a partly hydrogenated benzene nucleus. At present sufficient facts are not forthcoming whereby it is possible to state if this second benzene nucleus in quinine and cinchonine is hydrogenated or is a non-saturated fatty group.

—J. B. C.

Therapeutic Value of Quinine Salts. Boymond. Arch. de Pharm. 1887, 145.

THE author publishes in a tabular form the various recipes for quinine salts in the different Pharmacopœias, their formula, equivalent numbers, solubilities, water percentage and the percentage composition of acid and base. According to these tables the amount of pure alkaloid in the hydrate is 85·72 per cent.; in the acetate 84·37; in the hydrochloride 81·71; in the lactate 78·26; in the basic hydrobromide 76·60; in the valerianate 76·06; in the basic sulphate 74·31; in the neutral sulphovinate, 71·20; in the arseniate 69·38; in the basic salicylate, 68·79; in the citrate, 67·08; in the neutral hydrobromide 60·57; in the neutral sulphate (bisulphate) 59·12; in the hydroferrocyanide 56·52; in the hydriodide 55·95; and in the tannate 22·60 per cent.—G. H. M.

Emetine. H. Kunz. Arch. Pharm. 1887, 461.

EMETINE has hitherto been very little studied on account of the difficulty of obtaining it in a form sufficiently pure for analysis. The author now obtains it by a modification of Podwissotzky's method as a pure white, amorphous, electrical powder, which rapidly becomes yellow or brown on exposure to the light; it has a bitter and harsh taste. The *Emetinum purum* of commerce is a whitish-grey to greyish-brown powder. An examination of emetine, which, like quinine, is obtained from a Rubiaceæ, gave the following results:—

1. Emetine possesses the molecular formula $C_{30}H_{40}N_2O_5$ and gives a platinochloride with the composition $C_{30}H_{40}N_2O_5.H_2PtCl_6$. It is a diatomic base and also a tertiary diamine like quinine, since it yields by the addition of methyl an ammonium base *methyl-emetonium hydrate*, $C_{30}H_{40}CH_3N_2O_5OH$.

2. Emetine is very probably a derivative of quinoline, like quinine.

3. In addition to emetine the *Radix ipecacuanhæ* also contains bilineurin or choline.—G. H. M.

Ineïne from Strophanthus Hispidus. J. L. Soubeiran. Jour. Pharm. Chim. 1887, 593.

When the seeds are macerated with acidified alcohol a crystalline glucoside, *strophanthine*, is obtained, which by treatment with sulphuric acid is decomposed into glucose and *strophanthidine*. The latter is insoluble in water, easily soluble in alcohol and is particularly bitter. The tufts of hair of the seeds give, when treated with acidified alcohol, a crystalline substance of alkaloidal character, to which Hardy and Gallois have given the name *ineïne*. According to the author ineïne does not possess the physiological properties of strophanthine; he does not state, however, what properties it actually possesses. Helbing and Elborne could not find ineïne in the seeds.—G. H. M.

A False Kola-nut. E. Heckel and F. Schlagdenhauffen. Nouv. Remèd. 1887, 123.

According to the investigation of the authors, the fruit of *Heritiera littoralis Wight et Arn* is found mixed with kola-nuts. This substitution possesses a double interest, since both the plants named belong to the same family (*Sterculiaceæ*) as those which give the kola-nuts, and the fruits in question also serve as a food-stuff in India, and they possess exactly the same waste-repairing properties as the kola-nut. *Heritiera littoralis* is a large tree which grows in India, in the Philippines, Molucca, and other islands of the South Coast of Africa. The form of the nut is oval-pointed, it weighs 20—25grms. and is of a white colour, similar to the so-called Kola blanca. The cotyledons have, when chewed, at first an astringent, then a sweet, and, finally, a slightly bitter taste. The chemical examination of the fruit showed a complete absence of caffeïne in the nuts of *Heritiera littoralis*.—G. H. M.

Pterocarpin and Homopterocarpin. Cazeneuve and Hugounenq. Compt. Rend. **104**, 1722.

Cazeneuve showed in 1874 that there occurred in sandal-wood (*Pterocarpus santalinus*), in addition to santalin and santol, a beautiful crystalline substance, which he called pterocarpin. The authors have now extracted a second substance, which appears to be a close homologue of the first, and they now give the name pterocarpin to the new substance and call the earlier substance homopterocarpin. Powdered sandal-wood is intimately heated with an equal weight of slaked lime, moistened with water, dried in the water-bath and extracted with ether. The lime forms, with the colouring matter, a lake insoluble in ether, and, with the resin, a slightly soluble body. The ethereal extract is evaporated, the residue taken up with boiling alcohol of 93°, from which pterocarpin and homopterocarpin separate on cooling. They are again crystallised from alcohol, then from ether, and finally separated by cold carbon bisulphide, in which homopterocarpin is very easily soluble, and pterocarpin almost insoluble. 1kilo. of sandal-wood contains about 5grms. of homopterocarpin and 1grm. of pterocarpin.

Pterocarpin, $C_1H_8O_3$, is insoluble in water and cold alcohol, soluble in boiling alcohol, less soluble in ether and crystallises from chloroform in clino-rhombic prisms, which melt at 152°. The substance is neutral, is insoluble in acids and even in boiling concentrated potash solution, but it is decomposed by fused potash with the evolution of a coumarin-like odour. With conc. HNO_3 it gives a green coloration.

Homopterocarpin, $C_{12}H_{12}O_3$, is soluble in ether, chloroform, benzene and carbon bisulphide, less soluble in cold, more easily soluble in boiling alcohol. It crystallises from ether in beautiful long needles. It softens at 70°, begins to melt at 82°, completely melts at 86°, and, once melted, remains pasty for several days. It withstands boiling concentrated potash solution, but, when fused with potash, it yields carbonic anhydride and phloroglucinol and evolves an odour of coumarin. When heated for 10 hours with concentrated hydrochloric acid it yields a substance which appears to be a resorcinol ether $(C_6H_4.OH)_2O$, and, by further action, a strongly fluorescent substance and methyl chloride. This admits of the conclusion that homopterocarpin contains the resorcinol group and one or more methyl groups. It appears to resemble the internal anhydrides of the aromatic series, and particularly coumarin.—G. H. M.

On Peptones and the so called Peptones of Commerce. Gerlach. Chem. Zeit. **11**, 1246.

Peptones are the final active products of digestion. They are soluble in water and dilute acids, and diffuse through membranes. They appear to melt on the water-bath, but this apparent melting is owing to water, which they hold tenaciously enclosed. Peptones injected into the blood of dogs gradually cause narcose, and the blood loses for some time its power of coagulating. The peptones used as food therefore do not pass unaltered into the blood, but are changed in the cells of the intestines. They can be classed in three groups—pepsine-peptones, pancreas-peptones and peptones derived from vegetable ferments (*Carica papaia*, *Agave Americ.*). Whereas those of the first group have a pleasant taste, those of the second class of peptones taste and smell very disagreeably; the last has no practical value yet. As to the peptones of commerce, more especially the well-known preparations of Grübler, Sanders, Ezn, Witte, Kemmerichs and Koch, their name is a misnomer, since they contain scarcely any peptone but easily soluble albumen. Nevertheless, all these preparations are easily digestible and, therefore, a food which can be highly recommended to persons with a sluggish digestion and to convalescents.—S. H.

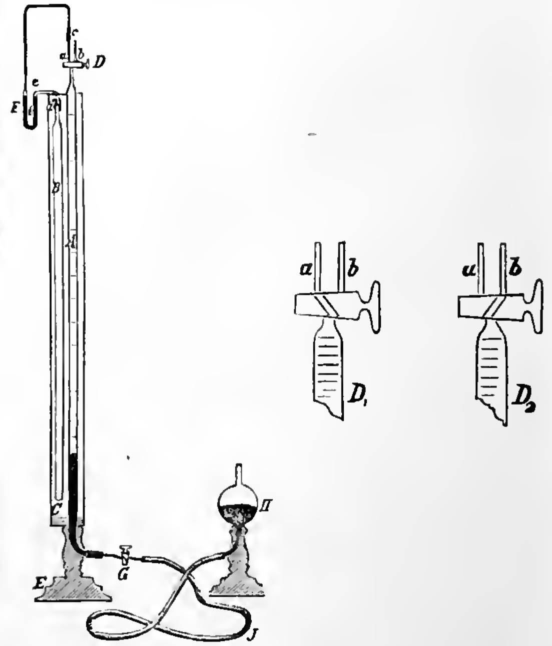
Improvements in Apparatus for Drying or Curing Fruit, Tobacco and other Substances. H. H. Lake, London. From H. C. Andrews, New York, U.S.A. Eng. Pat. 10,915, Aug. 9, 1887. 6d.

This apparatus consists of a closed chamber, in the lower portion of which is situated a hot-air pipe or heating flue. Above and parallel to this is another pipe provided with perforations and communicating with the exterior of the chamber. Cold air enters this latter pipe and escaping by the perforations mingles with the up current of hot air rising from the neighbourhood of the heating flue. The substance to be dried is contained in the upper portion of the chamber.—A. R. D.

XXII.—ANALYTICAL CHEMISTRY.

A Gas Burette Working Independently of Temperature and Pressure. W. Hempel. Ber. **20**, 2340—2343.

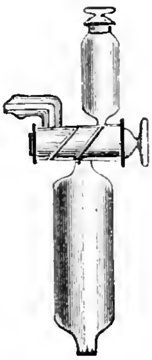
A is an ordinary 100cc. gas burette, fixed to a foot E, and closed above by a Greiner-Friedrich's three-way cock. The burette is connected by caoutchouc tubing with the gauge F and the tube B. The latter is a simple glass tube, which is closed below and communicates with F. The whole is contained in the vessel of water C. The tube C is open above and closed below by an indiarubber stopper with a single bore. The gauge tube F is about 6mm. wide at the bend; from *e* to *c* it is capillary if mercury is used, or 3mm. wide if water is the liquid employed. The burette is in connection with the tap G and the vessel H for adjusting the level. If the gas is measured in the moist state, a drop of water is introduced into B. The volume of the gauge tube between *f* and *c* must be measured once for all previous to use. This is done by drawing a given volume of gas into the burette, then placing the three-way cock in the position D_2, so that it communicates with the gauge. By raising or lowering the vessel H the pressure can be brought to that of the gas in B. When the pressure is equal the level of the mercury in both limbs of F is the same. The cock G is closed and the volume read off.



If G is again opened and H lowered, the liquid in the gauge can be brought to *e*. If the cock D is closed and the volume of gas again read off on the scale subsequently to adjusting the liquid in the vessel H, the difference of the two readings gives the volume between *f* and *e*. The operation of measuring gases is as follows:—The burette is first filled with the liquid, and is then connected by a capillary tube with the vessel, which contains the gas for analysis. The three-way tap must be in position D_2, so that the gas passes into the tube *b*. For measuring, the cock is put in position D. By raising or lowering the vessel H the liquid in both limbs of the V tube is adjusted to one level, the cock G is closed, and the volume read off. After measuring, the gas is withdrawn from the gauge tube.—J. B. C.

Improvement of Bunte's Gas Burette. Chem. Zeit. 11, 1225.

THIS very useful form of gas burette is greatly improved by the application to it of the new cock introduced by Greiner and Friedrichs (*Chem. Zeit.* 11, 53). The working of the apparatus is sufficiently illustrated by the figures.—A. G. G.



Congo-red as an Indicator. G. Vulpius. Ztschr. österr. Apoth.-Ver. 1887, 286.

TEST PAPERS prepared with Congo-red are sensitive not only to ordinary inorganic bases, but also to aniline and similar bodies and also to quinine, brucine, morphine, etc.; and are useful in cases where both litmus and phenolphthalein are unsuitable. The author, however, considers that its delicacy towards acid is not so great as that of carefully prepared litmus paper, since the latter will show slight traces of acid much quicker than the Congo-red paper. It is, therefore, not to be recommended for all pharmaceutical purposes.—G. H. M.

Detection of Indigo in Dyed Fabrics. W. Lenz. Zeits. Anal. Chem. 1887, 535—555.

THE following different qualities of indigo of undoubted genuineness were used in these experiments:—

1. Fine Bengal indigo.
2. Bengal indigo.
3. Oude indigo.
4. Kurpah indigo (violet).
5. Kurpah indigo (red violet).
6. Kurpah indigo.
7. Madras indigo (medium).
8. Madras indigo (ordinary).
9. Guatemala indigo (fine).
10. Bengal indigo (in powder).
11. Java indigo (fine).
12. Java indigo (common).

In the dyeing, a bath containing zinc dust and dilute soda solution was employed, as the property of the dye prepared by this method shows no abnormal action with reagents. In addition to these, fabrics dyed with commercial indigo carmine, Prussian blue, logwood extracts, and mixtures of these were also examined. The results are found in the following table This table shows an abnormality with indigo No. 11. It colours acidified alcohol similarly to cloth raised in logwood. As this property was only indicated when the cloth was dyed under certain conditions, the author considers that it is due to the presence of a colouring matter formed from the indigo. The other properties of the alcoholic extract do not, however, allow of any confusion. The test with concentrated sulphuric acid cannot be regarded as absolutely safe. If it is desired to test the dyed cloth instead of the extract, a sample is gently heated with an acid solution of stannous chloride. Prussian blue remains unchanged; indigo blue, indigo carmine and cotton blue are acted upon, and the cloth becomes bleached, whilst the solution is coloured yellow. Logwood is also discharged, and the solution acquires a pink colour. If hydrogen peroxide is added in excess to the stannous chloride extract, cotton blue gives a blue coloration and the pink colour with logwood is destroyed.

The indigo colour is not regenerated under these conditions. A more rational method, however, is to dissolve the colouring matter from the fibre, and for this purpose alcohol, which dissolves the aniline colours especially, and acidified alcohol, which indicates the presence of logwood colours, is used. The test with acidified alcohol is of considerable value. It must be borne in mind, however, that not all the aniline colours can be dissolved from the fibre with alcohol and, on the other hand, that indigo and indigo carmine are somewhat soluble. The action of acidified alcohol is still more complicated. The red reaction with logwood is produced in sufficiently concentrated solution, but changes on boiling to reddish yellow, a property which may be overlooked in testing indigo and indigo carmine with a hot solution of alcohol.

In such cases boiling glacial acetic acid, or concentrated formic acid, may be employed. Logwood colours the acid in the cold, pink, which, on heating, changes to yellowish red, but this colour is very rapidly masked by the indigo which subsequently dissolves.

These two solvents dissolve all the blue organic colours, with the exception of indigo carmine and Prussian blue, the first extract containing the largest quantity of logwood blue when present. If the acetic acid solution is mixed with ether and water added till the ether separates, the indigo remains in the ethereal solution, either dissolved or suspended. If, in addition to indigo, only logwood was present, the aqueous solution is coloured reddish yellow, and on the addition of concentrated HCl the aqueous solution becomes red. In presence of indigo carmine and cotton blue, logwood cannot be detected. In this case the ethereal solution is separated, and the aqueous solution shaken with chloroform or amyl alcohol, which dissolves out cotton blue. After separating the amyl alcohol the aqueous solution is shaken with an equal volume of dilute sulphuric acid, and if indigo carmine is present it now dissolves in amyl alcohol. If after treatment with glacial acetic acid insoluble blue colouring matter remains on the cloth, it may consist of indigo carmine or Prussian blue, which may be treated for and separated by one of the well-known reagents. Another method for separating the different blues is to treat the 4 sq. cm. of the cloth with 4cc. boiling hot borax solution. In this way logwood, indigo carmine and Prussian blue are dissolved, while cotton blue and indigo remain undissolved. To detect logwood in presence of indigo the cloth may be boiled with hydrochloric acid, in which case a red solution is obtained, or white alum with the formation of a blue solution, whereas indigo is undissolved. The examination of the absorption spectrum is also a useful guide for distinguishing these two colours. If the cloth is dyed with pure indigo it should give the following reactions:—Boiling water should not dissolve any colouring matter, nor spirits of wine (50—95 per cent.). Cold saturated solutions of oxalic acid, borax, alum, etc., should take up no colouring matter, nor should the borax solution on acidifying with HCl give a red colour, turning blue with Fe_2Cl_6. Stannous chloride and Fe_2Cl_6 should destroy the blue colouring matter on heating, and glacial acetic acid should dissolve the colour completely. No H_2S should be evolved on heating the cloth with concentrated HCl, nor should the carbamine reaction be given on heating the fabric with KOH and $CHCl_3$.

No.	Method of Testing.	Linen Strips dyed in the vat with various kinds of Indigo (already enumerated) and subsequently washed.		Cotton Yarn dyed with Indigo vat only, (*a*) Dark shade, (*b*) Light shade, both in an unfinished and finished sample.	Linen dyed with commercial Indigo Carmine (extract), with addition of Alum.	Linen dyed without Mordant in solution of Logwood, extracted by boiling.	Linen dyed with Logwood solution, and mordanted with Alum.	Linen dyed with Logwood solution, and mordanted with Copper Sulphate.
		Nos. I.—X., and XII.	No. XI.					
a	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*
1	The colour of the sample showed by daylight	Deep blue.	Deep blue.	(*a*) Deep blue. (*b*) Light blue.	Deep blue.	Yellow (reddish on washing with water).	Bluish red.	Blue.
2	About 1 sq. cm. of the dyed fabric, representing about 1 metre of the yarn threads, were treated for half-an-hour at the ordinary temperature with about 4cc. of 80 % spirits of wine, to which 1 % of HCl had been added. The solution appeared	Colourless.	Purple red to cherry red. Dilute ammonia gave a yellowish cloudiness. Ether removed the yellow colour from both the acid and alkaline solution. On adding HCl the layer of ether became red, but yellow again on shaking if too much HCl had not been added; the ether gave, however, no colour to the strongly acid solution.	Colourless.	Faint blue.	Red, solution changing to yellow on warming; red again on further addition of HCl, and purple red with ammonia; the latter colour was not permanent. Separation of a lake did not take place, even when ether was added.	Red, on warming the solution yellow, with more HCl red again. Ammonia precipitated a violet blue lake. A previous addition of tartaric acid hindered the separation of the lake; the solution appeared violet, but the colour soon changed. Ether also, without addition of ammonia, separated a lake of a red violet colour, which was changed to violet blue by ammonia.	As under 2*g*. Here also no lake was separated on addition of ammonia in excess, nor on the further addition of ether.
3	The samples of cloth (as in 2) were boiled with alcohol (80 %) to which 1 % of HCl had been added. The resulting extract separated from the cloth appeared	Light blue. Ammonia did not change the colour. Ether was coloured blue on being shaken up with the diluted solution; the solution itself became colourless.	Rather more of a blue-red than the foregoing sample, otherwise similar to 2*d*.	Light blue. Ammonia did not change the colour; ether was coloured blue on being shaken up with the diluted acid solution; the solution itself was thereby decolorised.	Light blue.	Yellow, but red with a further addition of HCl, otherwise as under 2*g*.	Yellow, but red with a further addition of HCl: otherwise as under 2*h*.	As under 3*g*.
4	The samples were with alcohol 80 % (as under 3) but with the addition of 4 % HCl. The solution appeared	As under 3*c*.	Decolorised, almost yellow brown, likewise the ether added to diluted solution; the latter did not appear red on addition of HCl. The solubility of the brown colouring matter in ether, the absorption spectrum of the solution, and the precipitation by water from an acid alcoholic solution, indicated a resinous product. This was found to be most readily obtained by reduction of indigo for 12 hours with zinc and caustic soda (isolated by means of mercury), and subsequent precipitation from the acidified and diluted alcohol by shaking up with ether.	As under 3*e*.	As under 3*f*.	As under 3*g*.	As under 3*h*. Ether, however, did not separate any lake from the acid solution.	As under 3*g*.

Linen dyed in the vat with Indigo and (*a*) topped with Logwood (*b*) same as (*a*), but mordanted with Alum (*c*) bottomed with Logwood.	Cotton Yarn vat-dyed blue and topped with Logwood, along with strip dyed with the vat employed both in an unfinished and finished sample.	Threads from the fabric of blue and white strips, which was to be tested for purity of Dyeing.		Cotton Yarn dyed with a cotton blue. (*a*) Light shade. (*b*) Dark shade. Each of the same in both raw and finished sample.	Linen treated alternately with solution of ferric acetate, and acid solution of potassium ferrocyanide—thus dyed with Berlin blue produced on the fibre.	REMARKS.
		Light blue threads.	Dark blue threads.			
k	*l*	*m*	*n*	o	*p*	*q*
(*a*) Dark blue. (*b*) Blue. (*c*) Dark blue.	Dark blue.	Light blue.	Dark blue.	(*a*) Light blue. (*b*) Dark blue (with a reddish copper glitter).	Deep blue.	
Purple red. Ammonia separated in (*b*) a violet dye-lake — hastened by diluting the solution with water and shaking with ether. In (*a*) and (*c*) ammonia produced no separation of lake, but only an alteration of the colour to bluish red.	Purple red, on warming yellowish red, and on addition of more HCl red again. Ammonia changes the colour to violet blue ; subsequent addition of ether facilitated the separation of a blue violet dye-lake, so that the lower solution appeared colourless.	Colourless.	Purple red, changing to yellow on warming, and red again on addition of HCl. Ammonia separated a violet lake, and more quickly when the diluted solution was treated with ether. Ether also separated a reddish violet lake from the acid solution ; an addition of ammonia changed the colour of the separated lake to a dirty violet.	Colourless.	Colourless.	On treatment with spirits of wine of 90 % strength, all the objects under examination imparted slight but not characteristic colourings, with the exception of the linen dyed with No. XI. indigo, described in column (*d*). This gave a red colour to the spirits of wine.
Blue red ; when shaken up with ether, the latter receives a distinct blue colour. Otherwise as under 2*k*.	More blue red than under 2*l*, owing to the indigo which is taken up by ether with a blue colour after previous addition of water. The solution mixed with the ether was coloured more distinctly red on further addition of HCl.	Light blue. On shaking, ether abstracted from the solution (previously diluted with water), its blue colour.	Blue red. The ether used for shaking with appears of a decided blue colour; the solution mixed with the ether acts towards HCl and ammonia in a similar manner to that described under 2*n*.	The solution appeared blue, but the yarn ceased parting with its colouring matter after a time, as shown when the solution was renewed.	Yellowish in consequence of a slight excess of iron oxide, which went into solution as chloride.	
As under 3*k*.	As under 3*l*.	As under 3*m*.	Without addition of ammonia, ether did not effect any separation of lake in the solution ; otherwise, the solution behaved as described under 3*n* and 2*n* respectively.	As under 3o.	As under 3*p*.	

No	Method of Testing.	Linen Strips dyed in the vat with various kinds of Indigo (already enumerated) and subsequently washed.		Cotton Yarn dyed with Indigo vat only. (*a*) Dark shade, (*b*) Light shade, both in an unfinished and finished sample.	Linen dyed with commercial Indigo Carmine (extract), with addition of Alum.	Linen dyed without mordant, in solution of Logwood, extracted by boiling.	Linen dyed with Logwood solution, and mordanted with Alum.	Linen dyed with Logwood solution, and mordanted with Copper Sulphate.
		Nos. I.–X. and XII.	No. XI.					
a	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*
5	The samples (as under 2) were boiled with about 4cc. of 20 % acetic acid.	The solution appeared blue, and gave up its colour to ether on being shaken with the same.	The solution became blue; ether absorbed the blue colour. the solution then appeared brownish. but more yellow on addition of HCl.	As under 5*c*.	The solution became blue (remained almost colourless when wool, dyed in a weak solution of H_2SO_4, was used instead of linen); ether, chloroform, and amylic alcohol did not take up any colour from either acid or alkaline solution. If, however, an equal volume of dilute H_2SO_4 was added, the colour was taken up by shaking with amylic alcohol (not with chloroform or ether).	The solution was coloured a yellowish red, and red on addition of HCl.	As under 5*g*.	As under 5*g*.
6	The samples (as under 3) were boiled with glacial acetic acid, and if a complete separation of the colouring matter from the fibre was desired, fresh quantities of glacial acetic acid were added, and the solution kept at the boil.	The samples were completely decolorised, and the acid coloured blue. Ether absorbed this blue colouring matter completely on dilution with water; chloroform, and amyl alcohol behaved in a similar manner to ether. The solution evaporated down with one of these solvents was neither coloured by HCl nor by ammonia, nor by alum solution after neutralising with ammonia. It gave, in fact, none of the reactions which are employed to indicate the presence of Campeachy, nor any reaction which could in any way interfere with the search for this colouring matter. The fibres, when completely decolorised by glacial acetic acid, did not give any red colour with HCl.	The samples were completely decolorised; the solution behaved as under 5*d*. After removing the blue colour by means of ether, the latter was coloured by HCl in a manner not characteristic, as described under 5*d*. The characteristic reactions for Campeachy would not be materially affected by the behaviour of this solution. When completely decolorised by glacial acetic acid the fibres did not give any red colour with HCl.	As under 6*c*.	The solution was slowly coloured blue on using linen which had been dyed the day previous, but which was quite dry. On using wool dyed at the same time in a weak solution of H_2SO_4, instead of linen, the acid remained colourless. Glacial acetic thus abstracted less colour than dilute acetic acid. On shaking up the diluted solution with ether, chloroform, and amyl alcohol, it behaved as described under 5*f*.	As under 5*g*.	As under 5*g*.	As under 5*g*.

Linen dyed in the vat with Indigo and (*a*) topped with Logwood (*b*) same as (*a*), but mordanted with Alum (*c*) bottomed with Logwood.	Cotton Yarn vat-dyed blue and topped with Logwood, along with a strip dyed with the vat employed, both in an unfinished and finished sample.	Threads from the fabric of blue and white stripes which was to be tested for purity of Dyeing.		Cotton Yarn dyed with a cotton blue, (*a*) Light shade, (*b*) Dark shade each of the same in both raw and finished sample.	Linen treated alternately with solution of ferric acetate, and acid solution of potassium ferrocyanide—thus dyed with Berlin blue produced on the fibre.	REMARKS.
		Light blue threads.	Dark blue threads.			
k	*l*	*m*	*n*	o	*p*	*q*
The solution appeared discoloured; ether abstracted from it blue colouring matter. The solution appeared then but slightly characteristic, but became red on application of HCl.	As under 5*k*.	The solution became blue, ether took up the colouring matter, thus decolorising the solution. The latter was not coloured even on addition of HCl.	The solution was coloured a dirty blue, and ether extracted from the same its blue colouring matter, and on shaking with ether and adding HCl, the solution was coloured red.	The solution was coloured blue with both samples, but ether did not abstract any colouring matter from the acid solution. On addition of caustic soda the solution was clouded brownish red, and ether took up the colouring matter with a yellow coloration. From an acetic acid solution the blue colouring matter could be abstracted by shaking with ether, chloroform, or amyl-alcohol.	The colour of the dyed sample remained unchanged, and the acid colourless.	
The solution became blue, and the sample decolorised after lengthy boiling; otherwise as under 5*k*.	As under 6*k*.	As under 5*m*.	By prolonged boiling the sample was completely decolorised; the solution behaved as described under 5*n*. A brownish-red colour of the sample was the longest to remain, but on removing the acetic acid by washing with water and heat-with dilute HCl, it disappeared at once, colouring the HCl red.	The sample of yarn was completely decolorised. On diluting with water ether only abstracted traces of a red colouring matter (presumably present as impurity) from the blue solution, whilst the whole of the blue colouring matter remained dissolved in the diluted acetic acid; it was, however, completely abstracted by chloroform, and with more certainty by amylic alcohol with a blue colour. The acid solution of the blue colouring matter separated, on addition of caustic soda in excess, a brownish-red colouring matter with a bluish glitter, which dissolves in ether with a yellowish brown, more easily in amylic-alcohol with a somewhat redder, and more easily still in chloroform with a red colour. If the ether, amyl-alcohol and chloroform were separated from the alkaline solution, acetic acid added to each, and the mixtures shaken with water, ether gave up the colouring matter again changed to blue, whilst chloroform and amyl-alcohol retained it in solution with a blue colour.	The sample and the solution were unaltered. On addition of 3 HCl to the acetic acid the material was decolorised on boiling, and the solution yellowish. On dilution with water, the solution was coloured blue.	

No.	Method of Testing.	Linen Strips dyed in the vat with various kinds of Indigo (already enumerated) and subsequently washed.		Cotton Yarn dyed with Indigo vat only. (a) Dark shade; (b) Light shade; both in an unfinished and finished sample.	Linen dyed with commercial Indigo Carmine (extract) with addition of Alum.	Linen dyed without mordant in solution of Logwood extracted by boiling.	Linen dyed with Logwood solution and mordanted with alum.	Linen dyed with Logwood solution and mordanted with Copper Sulphate
		Nos. I—X., and XII.	No. XI.

7	A sample of the object under examination (as under 2) was covered with concentrated formic acid of sp.g. 1·2, heated and extracted as in 6.	The acid was not coloured in the cold; on heating to the boil indigo was dissolved, and on repeated digestion completely extracted from the fibre.	As under 7*c*.	As under 7*c*.	The solution was coloured blue on being gently warmed; otherwise as under 7*c*.	The solution was coloured a beautiful red in the cold, and became yellowish-red on heating.	As under 7*g*.	As under 7*g*.
8	A small sample was boiled with 1·2cc. of cold saturated solution of oxalic acid.	The solution remained colourless, and was not changed by HCl.	As under 8*c*.	As under 8*c*.	The solution was coloured blue. The colouring matter was taken up by wool except for traces; more easily by linen.	The solution became reddish when cold, yellowish on heating, red on addition of HCl, red on addition of 0·05 — 0·1gr. crystallised ammonium molybdate, and violet if a quantity was added.	As under 8*g*.	As under 8*g*.
9	The samples (as under 2) were boiled with about 4cc. phosphoric acid.	The solution appeared colourless.	As under 9*c*.	As under 9*c*.	As under 5*f*.	At the commencement of warming the solution was coloured red, then yellowish-red. HCl effected a red coloration in the same manner as in the acetic acid solution.	As under 9*g*.	As under 9*g*.
10	A small sample was covered in a small porcelain dish with concentrated H_2SO_4.	The acid was coloured bluish-green, and became blue on dilution with water.	As under 10*c*.	As under 10*c*.	As under 10*c*.	The acid was coloured reddish-yellow.	As under 10*g*.	As under 10*g*.
11	A sample (as under 2) was boiled with about 4cc. of a 10% solution of pure potash alum in water.	The solution remained uncoloured.	As under 11*c*.	As under 11*c*.	The wool was coloured slightly blue. If wool was used instead of linen the solution was coloured even when the samples, after once boiling with alum solution, did not impart any further colour to boiling water.	The solution appeared of a purple-violet colour, and gave a purple-blue precipitate on addition of ammonia. Caustic soda produced a blue deposition which was soluble in excess (contrary to the statement in Dammer's "Lexicon der Verfaelschungen," p. 730).	As under 11*g*.	As under 11*g*.

Linen dyed in the vat with Indigo and (*a*) topped with Logwood, (*b*) same as (*a*) but mordanted with alum, (*c*) bottomed with Logwood.	Cotton Yarn vat-dyed blue, and topped with Logwood, along with a strip dyed with the vat employed, both in an unfinished and finished sample.	Threads from the fabric of blue and white strips, which was to be tested for purity of dyeing.		Cotton Yarn dyed with a cotton blue, (*a*) Light shade, (*b*) Dark shade, each of the same in both raw and finished sample.	Linen treated alternately with solution of ferric acetate and acid solution of potassium ferrocyanide — thus dyed with Berlin blue produced on the fibre.	Remarks
		Light blue threads.	Dark blue threads.			
k	*l*	*m*	*n*	*o*	*p*	*q*
The solution was coloured a beautiful red in the cold; on heating this became rather lighter, but was immediately concealed by the indigo blue going into solution. If the cold red solution was poured off and heated by itself, it assumed a yellowish red colour.	As under 7*k*.	As under 7*c*.	As under 7*k*.	The solution turned blue in the cold, and extracted the colouring matter easily and completely on warming. Ether extracted traces of a red colouring matter from the acid solution diluted with water; amyl alcohol extracted the blue colouring matter from the same.	The solution dissolved the colouring matter even on warming, and was not coloured blue on addition of chloroform. Even on addition of a little HCl, only a small quantity of Berlin blue was dissolved.	
As under 8*g*.	As under 8*g*.	The solution remained colourless and unchanged on addition of HCl.	As under 8*g*.	The colouring matter was easily and completely extracted from the fibre; the blue coloured solution did not impart the same to ether, though it did so to amyl alcohol.	The solution became distinctly blue, and the fabric of a brighter colour. On rubbing with water, it gave up some of its colouring matter mechanically.	
As under 9*g*.	As under 9*g*.	The solution remained colourless	The solution became coloured in quick succession red, and then yellowish red; likewise on using threads which had been previously extracted for 70 hours with boiling chloroform, HCl coloured the solution very distinctly red. On using phosphoric acid of 1 % strength, and then adding phosphoric acid of 20 % strength, the colours became very weak.	The solution remained colourless.	The sample and the solution remained unchanged.	
The acid was coloured green and became blue on dilution with water.	As under 10*k*.	As under 10*c*.	The acid was coloured green and blue on dilution with water.	The acid was coloured green, and on dilution with water blue.	The acid was coloured brownish green, and became blue on dilution with water.	The change of colour in the fabric could not be properly estimated, since the same was considerably influenced by mordants, especially iron.
As under 11*g*.	As under 11*g*.	The solution remained colourless	The solution was coloured purple red and gave a violet blue precipitate with ammonia; caustic soda also produced a blue precipitate. Much HCl coloured the solution red. If the solution of alum was treated with tartaric acid previous to addition of ammonia, no precipitate was caused by ammonia, but a very slightly constant, bluish red coloration.	The solution remained colourless.	The solution remained colourless.	

No.	Method of Testing.	Linen Strips dyed in the vat with various kinds of Indigo (already enumerated) and subsequently washed.		Cotton yarn dyed with Indigo vat only. (a) Dark shade; (b) Light shade; both in an unfinished and finished sample.	Linen dyed with commercial Indigo Carmine (extract) with addition of Alum.	Linen dyed without mordant in solution of Logwood extracted by boiling.	Linen dyed with Logwood solution and mordanted with alum.	Linen dyed with Logwood solution and mordanted with Copper Sulphate
		Nos. I.–X., and XII.	No. XI.					
a	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*
12	A sample (as under 2) was boiled with a solution of 1 part crystallised ammonium molybdate in 2 parts water.	The solution remained colourless.	As under 12*c*.	As under 12*c*.	The solution was coloured blue. The colouring matter was abstracted by wool except for traces—not so easily by linen.	The solution was coloured deep blue-violet.	As under 12*g*.	As under 12*g*.
13	A sample of the stuff (as under 2) was boiled with about 4cc. of a solution of borax. The borax solution employed was prepared by allowing a concentrated boiling solution of borax to cool and stand for several days at the temperature of the room, and then pouring off from the salt which had separated out.	The solution was colourless after filtration.	As under 13*c*.	As under 13*c*.	The sample was decolorised and the solution coloured blue. Ether chloroform and amylic alcohol did not take up the colouring matter even when acidified with acetic acid. Amylic alcohol, however, took up the indigosulphoacid with a bluish-green colour on addition of a quantity of dilute sulphuric acid.	The solution appeared yellowish, and was coloured red by HCl. The addition of 10% alum solution in excess first produced a colourless gelatinous precipitate, and a few minutes later a purple-violet coloration. This was changed to blue on the addition of ammonia.	As under 13*g*.	The reactions described under 13*g* were noticed here also, but with somewhat less distinctness.
14	A sample was gently warmed with an acid solution (1 in 10) of tin chloride.	The sample of stuff was decolorised and the solution became yellowish. On addition of hydroxyl in excess no change was perceptible in the colour of the liquid.	As under 14*c*.	As under 14*c*.	As under 14c.	The solution was coloured a beautiful rose-red, the fabric being decolorised. The rose-red colour was completely destroyed on warming with hydroxyl in excess.	As under 14*g*.	As under 14*g*.
15	Single untwisted and dissevered threads of the cloth or yarn in consideration were boiled with several cc. of a mixture of 10cc. iron chloride solution, 90cc. water, and 10 drops HCl.	The threads were decolorised.	As under 15*c*.	As under 15*c*.	As under 15*c*.	The threads were coloured gray, the solution blackish-green.	As under 15*g*.	

Various Reactions of Vanadates, and their employment in Analytical Chemistry. A. Carnot. Compt. rend. **104**, 1803.

The determination of vanadic acid in its alkaline and ammonium salts is very easily performed in the form of barium vanadate (see this Journal, 1887, 679). If the solution be acid, it is neutralised with ammonia, the solution at first remains yellow but on boiling it quickly becomes colourless. Barium chloride is then added, the liquid stirred, allowed to settle and tested with a little more reagent; there should be only a very slight smell of ammonia. The flask is then corked and quickly cooled. All the vanadic acid separates, as barium vanadate, $Ba_2V_2O_7$. If the liquid is boiled for some minutes after precipitation, the precipitate becomes denser and can be easily separated by decantation. Strontium salts give no precipitate in slightly ammoniacal solutions of vanadates, which have been saturated with ammonium chloride (provided that the solutions contain no carbonate and are not exposed to the air), although phosphates and arseniates are precipitated by strontium salts under these conditions. On this is based the separation of vanadic acid from phosphoric and arsenic

Linen dyed in the vat with Indigo and (*a*) topped with Logwood, (*b*) same as (*a*) but mordanted with alum, (*c*) bottomed with Logwood.	Cotton Yarn vat-dyed blue, and topped with Logwood, along with a strip dyed with the vat employed, both in an unfinished and finished sample.	Threads from the fabric of blue and white strips, which was to be tested for purity of dyeing.		Cotton Yarn dyed with a cotton blue (*a*) Light shade, (*b*) Dark shade, each of the same in both raw and finished sample.	Linen treated alternately with solution of ferric acetate and acid solution of potassium ferrocyanide — thus dyed with Berlin blue produced on the fibre.	REMARKS.
		Light blue threads.	Dark blue threads.			
k	*l*	*m*	*n*	o	*p*	*q*
As under 12*g*.	As under 12*g*.	The solution remained colourless	As under 12*g*.	The solution remained colourless, or assumed a rather brownish tint.	The solution remained colourless, and was not coloured blue on addition of ferric chloride.	
As under 13*g*.	As under 13*g*.	The solution appeared colourless after filtration.	The solution was coloured rather yellow, and became red on addition of HCl. Alum solution (of 10 % strength) in excess produced in addition to gelatinous precipitate, a purple violet coloration, which was changed to a blue precipitate on addition of ammonia.	The solution showed a slight reddish cloudiness, and appeared colourless after filtration.	The sample was decolorised to a rusty red condition. The solution was coloured slightly blue if a few drops of HCl were added (if filtered before the addition of HCl it remained colourless), and became deep blue on addition of ferric chloride.	
As under 14*g*.	As under 14*g*.	As under 14c.	The solution was coloured rosy red with decolorisation of the fibres. Hydroxyl destroyed the colour, with formation of an inconsiderable brownish cloudiness.	The solution was coloured yellow, whilst the yarn became colourless. Hydroxyl in excess coloured the solution blue.	The blue colour of the sample remained unchanged.	
No characteristic difference from 15c.	As under 15*k*.	As under 15c.	As under 15*k*.	On using about 3m. threads and 5cc. solution, the latter was coloured a bluish red; on dilution with three times the volume of water more blue; on addition of spirits of wine light green. The threads however were not decolorised on lengthy boiling. Ether did not extract any blue colouring matter from the coloured solution; chloroform extracted a little, and amyl-alcohol a quantity. Chloroform absorbed the colouring matter from the extract treated with alcohol.	Threads and solution remained unchanged.	

—J. B. C.

acids. The same reaction also serves for the very close separation of vanadic acid from molybdic and tungstic acids, since both these acids are almost completely precipitated by strontium salts in weak ammoniacal solutions, in presence of ammonium chloride. This reaction also admits of application for the separation and estimation of barium and strontium. Ammonium chloride is added to the solution and then ammonia free from carbonate, a dilute solution of ammonium vanadate is now added and the solution boiled for some minutes, when the barium is completely precipitated, whilst the strontium remains in solution. The liquid is cooled out of contact with air, decanted, the precipitate washed with cold water and the strontium precipitated in the filtrate by means of ammonia and ammonium carbonate, and weighed as strontium carbonate. The barium vanadate is dissolved in dilute hydrochloric acid, precipitated and weighed as sulphate. The method gives good results.—G. H. M.

An Error in Gas Analysis. W. Hempel. Ber. **20**, 2344.

CUPROUS CHLORIDE absorbs ethylene gas; it is therefore necessary to absorb the hydrocarbons in generator gases previously to determining carbon monoxide. If this is not done the carbon monoxide liberates the previously absorbed ethylene, and the volume of gas when passed back to the burette is often found to increase instead of diminish.—J. B. C.

Apparatus for Testing Producer-Gas and Water-Gas. F. Fischer. Ber. **20**, 2551—2553.

FOR the accurate testing of producer or water-gas, the author strongly recommends the apparatus shown in the diagram. The tube M is filled with mercury by raising the mercury bottle L and opening the taps *h* and *d*. *h* is then shut off, and *d* so regulated that it connects A and the indiarubber tube *a*. The mercury is then made to rise through A to the tube *e* by raising F; the funnel *t* is filled with water, which is allowed to flow out through tap *n* and tube *a*, so that the latter remains full of water when shut by the clip. The sample of the gas to be tested is collected in a glass sphere with capillary ends. The indiarubber tube *a* is drawn over one end, while the other is placed in water. Both points are then broken off and the gas is aspirated into A. The taps *d* and *h* are turned 90°: the required quantity of gas is forced into M; *h* is then shut off and the rest of the gas and water in A is driven out through *h*. About 1cc. of potassium hydrate solution is introduced into A, the measured gas then forced from M into A and after being here deprived of its carbonic acid, is again measured in M. In the same manner, any oxygen present is absorbed by pyrogallic acid. In order to determine the combustible gases, the tube A is cleaned with water and pure oxygen introduced into A through *a*. The necessary quantity of oxygen is then driven over from A into M, while the rest of the oxygen in A is removed through *d* and *a*. After measuring, the mixture of gases in M is returned to A, to be there submitted to the electric spark. The contraction is read off, the carbonic acid formed determined by absorption and from these data the composition of the gas may be calculated. Producer-gas, from coal and wood, and water-gas tested by this apparatus, had the following composition:—

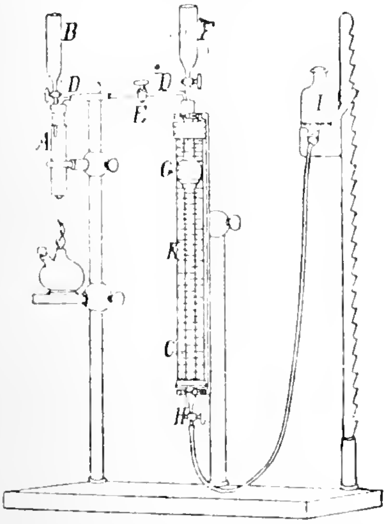
	Gas from Coal.	Gas from Wood.	Water-Gas.
CO_2	5·06	6·95	2·74
CO	21·58	28·60	43·75
CH_4	2·94	2·20	0·34
H	5·66	8·54	49·17
N	64·79	53·74	4·06
	100·00	100·00	100·00

—S. H.

A Volumetric Method for the Determination of Carbon in Iron. Dingl. Polyt. J. **265**, 502—507.

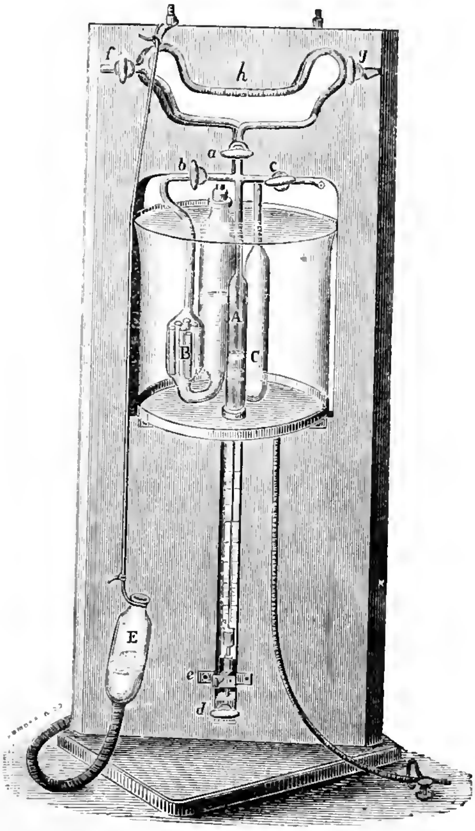
THIS method, which is due to J. Wiborgh, of Stockholm, differs from existing processes, in which the sample is treated first with copper sulphate and afterwards with a mixture of chromic and sulphuric acids, chiefly in measuring the volume rather than the weight of carbon dioxide produced. A considerable economy in time, labour and apparatus is thus effected, and a more delicate measurement obtained—*e.g.*, $\frac{1}{20}$cc. of CO_2 from 0·2grm. of iron represents 0·014 per cent. of carbon, but weighs only 0·0001grm. It is essential that the carbon shall be completely burnt to dioxide and in view of this the following three points must be borne in mind:—(1) Solutions of copper sulphate, even though neutral, cause an evolution of hydrocarbon from the metal and consequently a loss of carbon; but this occurs in appreciable quantity only when steel, cooled from a red heat without working, or grey cast iron are treated. In such cases the solution in the sulphate should not be urged to completion. (2) Hydrocarbons will be evolved even in the chromic acid solution, unless the iron has been sufficiently coated with a protecting film of copper in the first stage of the process. This is due to the fact that the sulphuric acid attacks the iron vigorously, even in the cold, but the hydrocarbons produced cannot be oxidised by the chromic acid except the liquid is nearly at a boiling temperature; thus they must escape until the solution has attained the necessary temperature for their oxidation. But since the deposited copper also resists solution until the same point is reached, it will protect any kernel of undissolved iron until such time as complete oxidation of the carbon is ensured. (3) The iron must ultimately be completely dissolved; the metal should therefore be sufficiently finely divided to pass a sieve with 1·5mm. perforations.

The apparatus required is shown in the accompanying block. A test tube A, 140mm. long by 20mm. internal diameter, is surrounded by a cage of brass wire gauze, and fitted with a good caoutchouc cork with two perforations. Through one perforation passes the narrow end of the stop-cock funnel B, which should project for about 15—20mm. beneath the cork; through the other, but not projecting beneath the stopper, passes the connecting tube D. The latter tube (D) consists of two portions, united by india-rubber tubing; the part more remote from A and carrying the stop-cock E, is bent to pass through one of the perforations of another caoutchouc stopper in the graduated tube C, the other perforation serving to connect the latter with a stop-cock funnel F. The tube C should for the distance of 70mm. downwards have an internal diameter of 16mm.; it should then be widened to a bulb G of about 25cc. capacity, and be finally reduced for the remaining 200 mm. to about 9mm., this narrow portion being graduated into $\frac{1}{10}$ths or, preferably, $\frac{1}{20}$ths of a cc. divisions denoting in each case the capacity of the whole of that portion of the tube above the respective graduations. Beneath this tube is the stop-cock H, communicating by flexible tubing with the movable water reservoir I. The test tube A is warmed by a gas or spirit lamp and the whole apparatus should be mounted on a suitable stand. The measuring tube is surrounded with a water jacket K to preserve an even temperature. To conduct an analysis, 0·2grm. of finely divided wrought iron or steel, or 0·1grm. of cast iron are introduced carefully into the open test tube A, taking care that none of the filings adhere to its sides; 4cc. of a saturated solution of pure crystallised copper sulphate are then introduced and allowed to act with frequent stirring during ten minutes, unless an appreciable smell of hydrocarbon be observed, when the action must be suspended after three or four minutes. 1·2grms. of crystallised chromic acid are added to the solution, when considerable heat will be evolved, which will necessitate cooling the liquid by plunging the tube into cold water. Meanwhile the tube C must have been filled with water by raising the reservoir I until the liquid has risen above the bulb G, the remaining space up to the cock being filled by water introduced through F. The test tube is now corked and connected with the burette C. 8cc. of sulphuric acid (1·7 sp. gr.) are introduced drop by drop into A through B, the cock of the latter is closed, that marked E opened and the liquid in the test tube gradually raised to boiling, the pressure having been diminished by previously lowering the water reservoir I. After ten minutes' boiling, during which the reservoir has been still further lowered, if necessary, to maintain the diminished pressure, the tube is cooled somewhat and together with the connecting tube D is carefully filled with water introduced through B. The cock E is then closed and the total volume of air and carbon dioxide read off after levelling with the reservoir. I is then once more lowered and the cock H closed, in order to draw in a quantity of a 10 per cent. hydrate solution through F. After the carbon dioxide has been completely absorbed, H is reopened, the liquid levelled again and a reading of the amount of residual air is taken. The difference between the two readings will be the volume of carbon dioxide evolved from the carbon in the iron. Evidently if 0·2grm. of substance were used, each cc. of CO_2 will correspond to 0·253 per cent. of C, and the factor 0·253 multiplied by the number of cc. of gas should give a direct reading of the percentage of carbon. But this is not quite correct, since a certain quantity of CO_2 (to be found only by experiment) is absorbed by the water in the tube. By treating pure anhydrous sodium carbonate in the apparatus instead of iron and comparing the actual with the theoretical yield of carbon dioxide the factor may be corrected. Thus the true factor was found to be 0·28 and this was universally correct for cast irons; but for wrought irons or steel, which contain less carbon, it should be 0·29. When 0·1grm. of iron is used the factor must, of course, be doubled. Where the temperature of the operation differs much from the normal 18°, correction must be made by multiplying or dividing by $(1 + 0{\cdot}00367 \times t)$ where t is the variation in temperature, according as the solution is cooler or warmer than the normal. A table of results obtained with many irons and steels, estimated both by this and other processes, shows a striking agreement in each case between the old and the new methods.—W. G. M.



Portable Apparatus for Determining Carbon Dioxide in Air. O. Petterson and A. Palmquist. Ber. **20**, 2129—2134.

The apparatus is shown in the diagram. An oblong wooden box, not given in the figure, is screwed to the wooden stand. The sample of air enters A, and is measured off here by means of the graduated scale both before and after absorption of the CO_2. The absorption of CO_2 is carried out in B. By raising or lowering E, which contains mercury, the measuring pipette may be filled with either mercury or air. A drop of water is always kept on the surface of the mercury. In adjusting the meniscus of the mercury previous to reading off, the pressure in A is made equal to that in C. A differential gauge containing a drop of coloured liquid (azobenzene dissolved in petroleum) communicates on the one hand with A and on the other with C by means of a capillary tube *h*. By moving the reservoir E and finally (after closing the cock *d*) the screw *e*, the level of mercury in A is adjusted, so that the drop of liquid in the gauge remains at zero. In this way, as the air in A and C is shut off from outside throughout the experiment, and as the temperature is maintained constant by means of the water in the surrounding vessel, temperature and pressure may be neglected. The correction for saturation of the air with moisture may also be neglected. In the analysis three operations are necessary:—(1) Air is drawn in by adjusting the mercury level to zero on the scale. The cocks *f*, *g*, *b*, *c*, *d* are closed. (2) The cocks *d* and *b* are opened, *a* is closed and the air driven into A from B. In one or two



minutes the CO_2 is absorbed: the air is passed back into A, *b* is closed, *a* opened, and the mercury level in A adjusted so that the index of the gauge is normal. The diminution in volume is then read off on the scale.
—J. B. C.

Estimation of Calcium in Thomas-slag, as well as in Phosphorite and Similar Minerals. H. Immendorff. Landwr. Versuchsst. 1887, 377.

The following method is recommended for the rapid estimation of calcium in presence of iron and phosphoric acid. The substance is dissolved in hydrochloric acid, excess of ammonia added, the mass neutralised and made just acid to litmus. It is then warmed, precipitated by ammonium oxalate, diluted considerably and when cold, filtered, etc. The precipitate is dissolved in dilute sulphuric acid, titrated with potassium permanganate and the quantity of calcium calculated from the numbers obtained.—D. A. L.

The Examination of Ether. G. Vulpius. Chem. Zeit. 11, 1246.

Previous to the last rectification the ether should always be treated with some fused potassium hydrate. Ether thus prepared and kept in the dark will not liberate iodine from potassium iodide. In examining ether as to its purity, the following tests should be made:—(1) 5cc. of ether are allowed to evaporate until the residue only amounts to 0·1cc. This residue should be neutral to litmus paper. (2) 10cc. of ether shaken with some water and 0·1cc. of decinormal potassium hydrate and a trace of phenol-phthaleïn should turn red. (3) Potassium hydrate treated with the ether in question should not turn yellow within one hour. (4) 10cc. of ether shaken with 1cc. of a 10 per cent. potassium iodide solution in a small glass-stoppered bottle must show no coloration within one hour.—S. H.

On the Estimation of Paratoluidine in Aniline-for-red. C. Haüsserman. Chem. Zeit. 11, 1223.

Of the various analytical methods which have up to the present been proposed for the estimation of the constituents of aniline-for-red, not a single one is capable of yielding even approximately correct results. The method of Schoop (*Chem. Zeit.* 9, 1785), which depends upon the separation of the paratoluidine as the acetyl-derivative, has of late been much employed for the commercial valuation of aniline oils. The great discrepancies which have arisen have led the author to make a critical examination of the method with known mixtures of pure aniline, orthotoluidine and paratoluidine. The extremely incorrect results obtained show that the method is utterly unreliable.

Mixture.	Paratoluidine found.
21 per cent. paratoluidine 42 per cent. orthotoluidine 34 per cent. aniline	19 per cent.
6 per cent. paratoluidine 44 per cent. orthotoluidine 50 per cent. aniline	0 per cent.
10 per cent. orthotoluidine 90 per cent. aniline	22 per cent.

The numbers found are the mean of several determinations.—A. G. G.

Examination of Narcotic Extracts. H. Beckurts. Chem. Zeit. 11, 1245.

The author examined the different methods published for the determination of alkaloids. None of them could be considered accurate or simple. He therefore, in conjunction with Holst, worked out another process, as follows:—(1) For extracting strychnine 2grms. of the finely-powdered extract are shaken with 5cc. of water, 5cc. of ammonia and 10cc. of alcohol until all is dissolved. The solution is thrice shaken with 20, 10 and 10cc. of chloroform respectively. The chloroformic extract is collected and deprived of the solvent by distillation. The residue is dissolved in 15cc. of decinormal hydrochloric acid and filtered; after washing the filter with water, the filtrate is titrated with normal sodium hydrate solution, cochineal being used as indicator. The number of cc. of sodium hydrate required deducted from 150 and the rest multiplied by 0·00364, yields the amount of alkaloids in grms., which figure multiplied by 50 gives the percentage of strychnine and brucine in the solid extract. (2) For Extr. Hyoscyami, Belladonnae, Aconiti, 2·5grms. of the extract are dissolved in 3cc. of alcohol and 6cc. of water. 1cc. of ammonia is added to the solution and the latter shaken thrice as above with 20, 10, and 10cc. of chloroform. After distilling off the solvent the residue is dissolved in 5cc. of decinormal hydrochloric acid, filtered and the filtrate titrated back with centinormal sodium hydrate. The number of cc. of sodium hydrate used, deducted from 50, yields the number of cc. of hydrochloric acid required for neutralising the alkaloids.

$$1\text{cc. of centinormal HCl} = \begin{cases} 0{\cdot}00289 \text{ atropine.} \\ 0{\cdot}00289 \text{ hyoscyamine.} \\ 0{\cdot}00533 \text{ aconitine.} \end{cases}$$

The same method is not suitable for *Extr. Conii* owing to the volatility of coneïne. The titrated solutions may be further examined for the different alkaloids, after making them alkaline with sodium hydrate, extracting with chloroform and driving off the latter.—S. H.

Action of Oils on Polarised Light. W. Bishop. Jour. Pharm. Chim. 1887, 300.

Vegetable oils, with the exception of castor and resin oils, are generally supposed to be optically inactive. The author, however, has obtained the following results from filtered oils, using a Laurent saccharometer, with a tube 20cm., at a temperature of 13 to 15 degrees:—

Nature of Oil.	Rotation in Saccharometer-Degrees.
Sweet Almond	—0·7°
Earth-nut	—0·4
Colza (German)	—2·1
Colza (Japanese)	—1·6
Linseed (not German)	—0·3
Nut	—0·3
Poppy	—0·0
Olive	+0·6
Sesame (various samples)	from +3·1 to + 9·0

Hence, if a sample of oil, linseed oil for example, has a right-handed rotation, this may be due to adulteration with either resin oil or sesame oil, or a mixture of the two. Therefore it is important to test for the sesame oil in such cases.—D. A. L.

Estimation of Sugar in Beets. Böhm. Ztschr. f. Zuckerind, 11, 531.

A convenient quantity of beet-magma is weighed and placed in a graduated flask, allowing 100cc. for every half of the normal quantity of beet-magma taken; the flask is filled to the mark with water at 70 degrees, air-bubbles being brought to the surface by whirling and these broken down with ether. After fifteen minutes' standing, the mass is cooled and the flask re-filled to the mark with lead acetate. The filtrate is polarised in a 40cm. tube. To correct for volume of the beet marc, multiply result by 0·997, or add beforehand 0·3cc. for every half of the normal quantity of beet magma taken. According to Herles, results by this method agree very closely with those from alcohol extraction and other methods. Lead acetate must not be added earlier in the operation, nor must the mass be heated with lead acetate, otherwise the results will be incorrect.—D. A. L.

Presence of Copper in Coal and Coke. B. Platz. Stahl. and Eisen 1887, 258.

The author states that copper occurs in all the varieties of Westphalian coal. The mean of twelve analyses gave 0.032 per cent. The quantity, however, is too small to affect the iron smelted with this coal and the coke prepared from the coal.—G. H. M.

Improved Method of and Apparatus for Testing Gases drawn from Mines, and Signalling or Indicating the Result thereof, and for General Signalling in Mines. T. Shaw, Philadelphia, U.S.A. Eng. Pat. 3531, March 8, 1887.

The purpose of the patent is to draw off gases from the mine for testing and indicating the result by signal. The following apparatus is used. A pipe communicates from the ceiling of the mine with the top of the shaft. This pipe is in communication with an exhaust pump, and a small pipe leads from the exhaust pump to a metallic cylinder having a contracted opening on one side opposite a flame and at one end a loose piston valve opposite a gong with a spring for retracting this piston valve. If the gases from the mine which are driven into the cylinder form an explosive mixture, they will explode on coming in contact with a flame, and the piston will be driven against the gong. Each gun is provided with means to prevent the flame from travelling back to the mine. The construction of the apparatus may be seen from the diagram. It consists of a cylinder *p* closed at one end by a piston *s*, which also serves as a valve, and is pressed against the cylinder by a bow spring *t*. The gas is pumped in through *b*. The explosion forces the piston against the gong and at the same time raises the valve *a* to the position indicated by the dotted lines, so that when several gongs are sounded, the attendant may know with which mine to communicate. To prevent the flame from travelling back, the valve *y* (Fig. 2) is placed in front of the pipe communicating with the mine. The valve is hinged at the bottom and opens inside the cylinder, so that the pressure of the explosion causes it to close. The pipe is provided at the mine end with a whistle, so that by reversing the exhaust-engine, air is blown into the mine and the whistle sounded.

New Books.

A Short Manual of Analytical Chemistry, Qualitative and Quantitative—Inorganic and Organic. By John Muter, M.A., Ph.D., F.R.S.E., etc. Third Edition. Illustrated. London: W. Baxter, Secretary. At the Offices of the School of Pharmacy, 325, Kennington Road. Simkin, Marshall & Co., Stationers' Hall Court, E.C.

8vo volume, bound in cloth, containing Preface, Table of Contents, 195 pages of subject matter, and an Alphabetical Index. Interspersed with the text are 46 wood engravings. As might be expected from a man with the author's reputation, special attention is given to the important subjects of the analyses of Water, Air and Food, and especially of Drugs, Alkaloids, Urine and Urinary Calculi. This fact will justify the confidence of medical students and those engaged in pharmacy. Of particular interest is the portion devoted to the Micro-Chemical Identification of Drugs, with the tabulated engravings showing the crystalline appearances of the same under the microscope. The work as a whole is embodied as follows:—Part I. treats of Qualitative Analysis, which is again subdivided and headed thus: Processes employed by practical chemists; Detection and Separation of the Metals; Detection and Separation of Acidulous Radicals; Qualitative Analysis, as applied to the Detection of Unknown Salts; Qualitative Analysis of Alkaloids and of the so called "Scale" Medicinal Preparations containing them, with a General Sketch of Toxicological Analysis. Part II.—Quantitative Analysis. Weighing, Measuring, and Specific Gravity; Volumetric Quantitative Analysis and Use of the "Nitrometer"; Gravimetric Quantitative Analysis of Metals and Acids; Ultimate Organic Analysis; Special Processes for the Analysis of Water, Air, and Food; Special Processes for the Analysis of Drugs, Urine, and Urinary Calculi; Analysis of Gases, Polarisation, and Spectrum Analysis. The published price of this work is 6s. 6d., that for students and those outside the trade 5s. 6d.

Exercises in Quantitative Chemical Analysis, with a short Treatise on Gas Analysis. By William Dittmar, LL.D., F.R.S., Professor of Chemistry in the Glasgow and West of Scotland Technical College. Glasgow: William Hodge & Co., 123, Hope Street. 1887.

This excellent treatise takes the form of an 8vo volume bound in cloth, with preface, tables of contents and of the atomic weights and 313 pages of subject matter. The work terminates with an alphabetical index. It may also be noted that the last twelve pages of subject matter are devoted to notes on the matter of the preceding text, the whole of which is divided into "exercises" which are individually numbered and definitely headed. These notes are somewhat similar to those found at the end of Fresenius' large "Treatise on Quantitative Analysis," but they are even more usefully conceived and clearly stated. The work is illustrated with 61 well-executed wood engravings. As regards the division of text into exercises, the principal divisions or groups are the following:—Exercises in Exact Weighing and Measuring; Exercises in Analytical Methods; Elementary Analysis of Combustible Carbon Compounds; Gas Analysis; Promiscuous Exercises in Applied Analysis; Notes.

Einfachere Gewichtsanalytische Uebungsaufgaben in Besonderer Anordnung Nebst Einleitung: als Vorwort: Einiges uber Unterricht in Chemischen Laboratorien Von Dr. F. Muck. Mit 17 Textabbildungen. Breslau: Verlag von Edward Trewendt. 1887.

This little book, bound in cloth, and of 8vo size, contains 69 pages of subject matter illustrated with 17 woodcuts. The text is subdivided into thirteen chapters, each devoted to the treatment and examination analytically of characteristic salts and compounds of the following metals and metalloids:—Sodium, potassium, calcium, copper, lead, iron, aluminium, manganese, magnesium, silicon, cobalt, nickel, antimony, arsenic. With regard to the treatment referred to, this consists of a series of exercises in the conversion by the best methods of the above elements into well-known and most characteristic compounds, with a view especially to throw light upon the usual analytical processes adopted in the separation from other and similar bodies, or in the absolute gravimetric determination. The little work might be designated an introduction to qualitative and quantitative chemical analysis for beginners. A book on this pattern might be of great service in schools.

Modern American Methods of Copper Smelting. By Edward D. Peters, jun., M.E., M.D. New York: Scientific Publishing Company, 27, Park Place. 1887.

8vo volume bound in cloth, containing preface, table of contents and 335 pages of subject matter, terminating with an alphabetical index. With the text are interspersed numerous woodcuts. In this work the processes of "wet extraction" are not treated of, but merely methods of smelting. The text is sub-divided into the following chapters:—Distribution of the Ores of Copper; Description of the Ores of Copper: Methods of Copper Assaying: The Roasting of Copper Ores in Lump

Form; Stall Roasting; Kiln Roasting; Calcination of Fine Ore and Matte; Chemistry of the Calcining Process; Smelting of Copper; Blast Furnaces of Brick; Blast Furnace Smelting; Reverberatory Furnaces; Treatment of Gold- and Silver-bearing Copper Ores; Bessemerising Copper Mattes.

Trade Report.

(From the Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

FRANCE.

Regulations respecting the Importation of Toys coloured with Poisonous Substances.

The following rules are to be observed on the importation of toys coloured with poisonous substances into France:—

1. It is forbidden to import toys coloured with arsenical colours (Scheele green, Schweinfurt green, metis green, &c.); salts of lead soluble in water and acids, as ceruse, read lead, massicot, chrome orange; salts of copper, such as blue ashes.
2. The following colours are allowed to be employed: Vermilion, neuter chromate of lead (yellow chromate of lead, chrome yellow), painted on with spirit or oil varnish.
3. White lead is admissible if applied with oil varnish for the manufacture of indiarubber balloons or tin toys.

Importation of Antipyrine.

The following is a recent decision of the Customs authorities:—

An article known as "antipyrine" is included in the category of "Chemical products not enumerated," duty 5 per cent *ad valorem*.

SPAIN.

Regulations respecting the Importation of Alcoholic Liquors.

See *Board of Trade Journal* for November, p. 169 *et seq.*

UNITED STATES.

Customs Decisions.

An article called *Soufre raffiné en masse*, which consists of the residue obtained in the process of sublimation in producing the substance known as "flowers of sulphur," and which is imported generally in the ground condition, is held to be exempt from duty, under the provision in the free list, section 632, for "sulphur or brimstone, not specially enumerated or provided for," the article being neither "sulphur, refined, in rolls," nor "sublimed, or flowers of sulphur," which are specially provided for in sections 77 and 78.

Certain so-called "recovered manganese," which is understood to consist of the product of manganese recovered from manganese after it has been used in the manufacture of chlorine, and which is, in fact, an oxide of that article, is held to be free of duty, under the provisions in the free-list, section 621, for "manganese, oxide, and ore of."

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

Imports into the United Kingdom from Spain.

PRINCIPAL ARTICLES.	Sept. 1886.	Sept. 1887.
Chemical products unenumerated ....Value	£3,829	£5,918
Copper ore and regulus ..Tons	2,852	1,896
Value	£56,231	£36,758
Manganese ore ....Tons	..	4
Value	..	£15
Pyrites of iron or copper...Tons	32,727	11,712
Value	£61,021	£71,779
Quicksilver ....lb.	..	..
Value	..	..
Rags, Esparto ....Tons	1,707	2,626
Value	£27,908	£16,337
Total Value	1886.	1887.
September	£719,560	£710,363
October	£910,778	£1131,399

Exports of British and Irish Produce from the United Kingdom to Spain.

PRINCIPAL ARTICLES.	Sept. 1886.	Sept. 1887.
Alkali ....Cwt.	23,660	27,522
Value	£8,677	£9,053
Caoutchouc manufactures Value	£1,656	£2,553
Cement ....Tons	1,330	250
Value	£2,378	£169
Chemical products and preparations (including dyestuffs) Value	£3,871	£1,268
Coal products (including naphtha and petroleum ....Value	£1,510	£351
Manure ....Value	£11,300	£3,627
Painters' colours and materials Value	£2,122	£2,111
Soap ....Cwt.	653	619
Value	£500	£187

September......	£328,166	£301,001
October	£301,133	£262,039

MISCELLANEOUS TRADE NOTICES.

THE INLAND REVENUE AND METHYLATED SPIRIT.

A new regulation has been issued by the Inland Revenue Board. Any person authorised to receive methylated spirit for use in any art or manufacture, will in future be restricted to purchasing the same from a licensed maker of the spirit — *B. and C. D.*, November 5, 1887.

ADULTERATION OF WINE IN SPAIN.

See *Board of Trade Journal* for November, p. 527 *et seq.*

SYNDICATE OF THE RHENISH-WESTPHALIAN SULPHURIC ACID MANUFACTURERS.

The price of sulphuric acid having sunk to a very low figure, the manufacturers of the northern part of the Rhine province and Westphalia have formed an association, with the object of raising the price of sulphuric acid on the 1st of January, 1888.—S. H.

COMMERCIAL RELATIONS BETWEEN RUSSIA AND ROUMANIA.

The Russian *Journal de St. Pétersbourg* for the 11th October last, quotes from the Roumanian *Express Orient*, of Bucharest, an article on the subject of the commercial relations between Russia and Roumania. The *Express Orient* considers that in the absence of any commercial convention with Austria, the present is a very opportune moment for cementing the commercial relations between Roumania and Russia. The recent Exhibition at Craiova was particularly rich in exhibits which proved the interest felt by Russian merchants, in favourably impressing the Roumanian market, and those exhibits were received with extraordinary favour. There is, in particular, an increasing demand in Roumania for Russian refined sugar, toilet soap, candles, naphthaline, and cigarette-paper. Each of these articles, the Roumanians are now finding, can be bought cheaper in Russia than in Austria. The *Express Orient* also believes that Russian merchants would find a ready sale for other exports, and especially for hardware and for chemical products, such as sulphuric acid. It believes that in Roumania there exists an immense field, hitherto almost unworked, for Russian commercial enterprise, and that a very little energy on the part of the Russians would be sufficient to persuade the Roumanians to purchase from Russia almost all the articles which are at present brought to them at great trouble and expense from western Europe.

ZINC FIELDS OF MISSOURI.

The following information, respecting the zinc fields of Missouri, was contained in *Bradstreet's* for the 8th October last:—

"The St. Louis *Globe-Democrat* states that in 1885 the world's production of zinc amounted to 291,609 tons of 2240 pounds each, 255,270 of which were obtained in Europe, and 36,339 in the United States. The principal zinc-producing states in this country are Illinois, Kansas, and Missouri, which stood in this order in volume of output in 1885. The production of Missouri was about one-ninth of that of the whole country in that year. In the order of importance, Missouri towns, in the Ozark zinc region, are Webb City and Carterville, Zincite, Joplin and Lehigh. The area of the zinc region, however, 'covers many counties and includes millions of acres of territory.' The zinc ores of Missouri are of every variety of carbonates, silicates, and sulphurets. The sulphurets are most abundant in Jasper and Newton counties. Other varieties are found in that region, but in small quantities. Zinc and lead ores crop out on the surface of the ground in Washington county, especially in the neighbourhood of Londale and Hopwell. These metals are plainly exposed to view above soil over many miles in that region."

THE CINCHONA TRADE OF CEYLON.

The following is a copy of extracts from the annual report of the Planter's Association of Ceylon for the years 1885—6 and 1886—7 :—

" *Year* 1885—86. *Cinchona.*—Notwithstanding the growing feeling that in a few years' time this product will again become of great value, there has been practically no furthur planting of cinchona. The need for money to plant tea, the slow growth of tea when covered by growing cinchona, as well as the dying off of the trees themselves are causes which have led to the enormous export of 13,736,171lb. for the past year against 11,865 280lb. for 1884. While a rise in price during the current year would lead to a considerable export there can be no doubt that the maximum production has been reached, and that ere long there will be a great reduction in the quantity exported. It may be doubted whether the acreage under cinchona is now one-fourth of what it nominally was four years ago.

" *Year* 1886—87. *Cinchona.*—The same causes which led to the large export during 1885, have occasioned a similar export during 1886, and consequently prices have fallen to a barely profitable point. It is impossible to say for how many months this export may continue, but it is unlikely to be for long, and it is maintained entirely at the expense of the future.

" The exports for 1886 were 14,675,663lb., against 13 736,171lb. in 1885."

SILK CONFERENCE AT THE MANCHESTER EXHIBITION.

The following is a summary of a report by Mr. Bateman, of the Commercial Department of the Board of Trade, upon the proceedings at the Conference of the Silk Section of the Manchester Exhibition for the promotion of the silk industries of the United Kingdom, which was held on the 21st of October last. Mr. Bateman attended the Conference with the sanction of the Board of Trade, and at the request of the Executive Committee of the Exhibition.

The object of the Conference, consisting of a very representative gathering of spinners, dyers, manufacturers, merchants, and retailers, to the number of three or four hundred, was to discuss the present depression in the silk industry, and to propose remedies for the same.

After the discussion of papers dealing with the various phases of the question, the chairman proposed what was to be the practical outcome of the meeting, namely, a resolution for the establishment of a silk guild.

The majority of the meeting appeared to favour the re-establishment of duties on silk manufactures, but did not submit any formal resolution to that effect.

Technical education in dyeing, design, and mechanism, and information as to new sources of supply of the raw material and of new markets for silk manufactures abroad, were among the objects which it was considered the proposed guild should assist, and a suggestion by Mr. Bateman that the association should include merchants and retailers as well as manufacturers, so as to bring the latter into closer touch with the consumers who use their goods, was very favourably received by the meeting, and ultimately adopted.

A resolution was finally passed that a committee of the exhibition, with certain names added, should form an association for the purposes described, and draw up rules.

As the result of a discussion on the subject of weighting silks, a further resolution was passed in favour of stamping the amount of dye in silks on the piece on importation into the country, or on leaving the manufactory. It was pointed out that this would be a most difficult and expensive regulation to enforce, since only very skilled analysts can distinguish the percentage of loading.

Other resolutions were adopted in favour of a Minister of Commerce and Agriculture being appointed, and of the Technical Education Bill of last session being passed. The Merchandise Marks Act appeared to be appreciated by most speakers.

THE DEVELOPMENT OF THE AMERICAN CHEMICAL INDUSTRY.

This is the title of a series of articles in course of contribution to the *Engineering and Mining Journal* by Dr. Francis Wyatt, and dealing thus far with the sulphuric acid manufacture in general, and the utilisation of pyrites for this purpose in particular.

Pyrites deposits are found in almost all the States of the Union, but only those in New Hampshire, Massachusetts and Virginia are actually worked to any extent. The following analyses give a good idea of the quality of these ores :—

	Sulphur.	Iron.	Copper	Zinc.	Arsenic	Silica.
Milan Mines, New Hampshire, No. 1..	46·0	40·0	3·7	4·0	trace	6·25
Milan Mines, New Hampshire, No. 2	35·0	30·5	5·0	8·0	nil	21·5
Davis Mines, Massachusetts	49·27	15·3	1·47	—	trace	3·83
Arminius Mines, Virginia..........	46·0	44·5	2·1	—	trace	7·40

The total domestic extraction used for acid-making in 1886 was estimated at 55,000 tons. This was supplemented by an importation of 57,000 tons, making altogether 112,000 tons, or rather less than one-tenth of the total quantity of pyrites consumed in the manufacture of sulphuric acid throughout the world, a fact which in itself indicates a lamentably backward condition of chemical industry, and one that is far from harmonising with the brilliant progress of the States in other departments of the arts and manufactures. Below are some interesting figures with regard to the distribution of the consumption :—

District.	Actu'l numb'r works	1881.	1882	1883.	1884.	1885.	1886.
Boston & E's't'n District	5	0	2 500	7,500	14,500	25,800	26,900
New York District	6	7,000	23,900	29,500	39,000	44,600	55,700
Philadelphia District	2	0	5,000	5,000	3,500	11,500	23,600
Baltimore and Southern States......	3	0	2,000	2,000	4,000	7,500	4,300
W'st'rn District	1	0	1,000	1,000	2,000	2,000	1,500
Total	17	7,000	28,900	45,000	65,000	91,400	112,000

It must, of course, be taken into consideration that in many cases the railway rates are so heavy that there is little difference in cost at consumers' works between pyrites sulphur and pure brimstone.

The following table, showing the comparative costs of producing one ton of 50° B. sulphuric acid from sulphur and pyrites in the district of New York or Philadelphia, will be interesting to English makers :—

BRIMSTONE (*short tons*).

1 ton brimstone thirds (98 % S) at $19	$19.00
50lb. nitrate of soda at 2½ cents per lb.	1.25
5 cwts. of coals, at say $4 per ton	1.00
Workmen's wages................................	2.25
Superintendence and management..............	2.00
General jobbing repairs..........................	0.50
Interest on capital of $75,000	4.60
Total	$30.60

Product = 4½ tons 50° B.—cost per ton, $6.80.

PYRITES (*short tons*).

2½ tons pyrites, 46 % sulphur, at 10 cents per unit..	$11.50
60lb. nitrate of soda, at 2½ cents per lb.	1.50
5 cwts. of coals, at say $4 per ton	1.00
Superintendence and management..............	3.00
Workmen's wages................................	2.00
General jobbing repairs	0.60
Interest on capital of $100,000	6.15
Total..................................	$25.75

Product = 4½ tons 50° B.—cost per ton, $5.5.

The concentration of chamber acid to brown oil of vitriol and rectified oil of vitriol is carried on pretty much as in England. The author is by no means favourably disposed towards concentration in platinum ; in fact, he estimates it to cost between 60 and 70 per cent. more than in glass. He says, however, that near New York a rectifying plant is at work upon a new principle, wherein cast iron is made to replace glass and platinum, and which bids fair to create as great a sensation as the introduction of the Glover tower.

The cupreous cinders are treated for the extraction of the copper by both wet and dry methods. The non-cupreous residues—especially from *smalls*—are often sufficiently low in sulphur to permit of their direct use in the manufacture of Bessemer pigs At the Lancashire Hill Chemical Works, Long Island, New York, where a Canadian ore containing about 3½ per cent. of copper and 13—14 per cent. silica is used, the residues are smelted (with the admixture of a small quantity of green smalls) in a Herreshoff water-jacket furnace, and a matte of 50—60 per cent. copper obtained with a loss of less than half a per cent. of copper in the slag. The average daily charges are :—

	48in. Furnace.	60in. Round Furnace.	Rectangular Furnace.
Pyrites cinders ..	51·7 tons	76·0 tons	76·8 tons
Green smalls	4·3 ,,	8·0 ,,	13 2 ,,
Sand..............	2·8 ,,	12·0 ,,	5·3 ,,
Iron slag	—	9·0 ,,	—
	50·8 tons	105·5 tons	95 3 tons
Coke	11·5 tons = 20%	17 tons = 16%	17·4 tons = 18%

Of the various wet methods in vogue, the author prefers that of Hunt and Douglas, wherein the copper is precipitated as sub-chloride by the agency of sulphurous acid gas.

Besides the 112,000 tons, pyrite, above mentioned, there was also used for acid-making in 1886, 90,200 tons of brimstone. Of the sulphuric acid produced four fifths were used in the manufacture of fertilisers or in petroleum refining, the remainder being distributed among the various smaller channels of consumption. —*Engineering and Mining Journal*, New York, Aug., Sept. and Oct. 1887. A. R. D.

STATISTICS.

ITALIAN CHEMICAL STATISTICS.

Official returns have been published relating to the Italian trade in chemical products during the first six months of 1887. In that period 1827 tons boracic acid were exported from Italy, against 1722 tons in the first half year of 1886 Of Italian refined borax 341 tons were exported. Formerly nearly the whole of the boracic acid produced in Italy was exported, but recently large works have been established in the country by the firm of Larderel, and a considerable part of the acid is now treated at these works. The export of cinchona salts from the Milan and Genoa works rose from 5000 to 10,000kilos. (176,500oz. to 353 000oz.). This includes, besides quinine sulphate, all the minor cinchona salts. The export of the latter bas been much assisted by the establishment of drawback on shipments abroad. The importation of soda nitrate, which is principally used in the manufacture of nitrate of potash by boiling with chloride of potash, rose from 2600 to 6100 tons. The cause of this advance is due to the increased requirements of gunpowder by the War Department. Soda imports rose from 910 to 1160 tons, caustic soda from 3800 to 4000 tons, oxides of iron and lead from 1100 to 1700 tons. The alum works of Civita Vecchia have not been so successful as was expected, it being found preferable to export the crude mineral. The shipments of winelees and argols rose from 3500 tons to no less than 11,200 tons. More lemon-juice was also exported—viz., 503 tons raw and 1892 tons concentrated juice, against 220 and 782 tons respectively. This enormous increase in the shipments is due to the large crop of "agrumi" and the cheapness of the lemons; but it seems inexplicable that under these favourable circumstances the manufacture of citric acid in Italy should still be so much neglected. Of common soaps, 1959 tons were exported in the first six months of 1887 and of medicinal preparations, 834cwt in the first half-year of 1886. The total value of the imports of chemical and medicinal products, resins and perfumery, was £1,000,000, the exports £1,160,000.

JAPAN.

Growing Drug Imports.

Hyogo imported in 1866, £72,036 worth of drugs, against £11,838 in 1885; of aniline dyes and paints, £12,934, and of other dyes, £28,912 were imported in 1886, against £25,085 in 1885.

Drug Exports.

The exports from Hyogo in 1886 show the following results as compared with the preceding year:—

	1886.			1885.	
	tons	£		tons	£
Antimony	1,928	25,513	..	2,195	35,764
Camphor	2,328	114,789	..	1,393	59,082
Soap (washing)	1,871	8,567	..	1,991	10,890
Vegetable wax	1,199	51,643	..	1,183	57,003

Drug Statistics.

The following figures relate to the imports of drugs, etc., into Yokohama:—

	1886.		1885.
			£
Mercury lbs.	112,731	10,413	..
Drugs and medicines ,,	..	102,920	60,002
Dyes, aniline cwts.	1,468	25,044	19,185
Dyes and paints	..	26,020	29,441
Indigo cwts.	797	17,514	..
Logwood extract lbs.	944,123	13,418	..
Eastern drugs and medicines lbs.	..	20,744	15,186

The Exports include:—

	1886.		1885.	
			£	£
Drugs and medicines	..	16,180	..	26,613
Fish oil ......gall.	373,810	13,967	gal. 408,533	16,893
Peppermint oil ,,	9,040	9,678	..	..

Medicine Imports.

Amongst the miscellaneous foreign imports not considerable enough in value to rank as staples, the most noteworthy item during the past year was undoubtedly drugs and medicines, of which over £100,000 worth were imported, as against only £60,000 worth in 1885.

Other Drugs.

Of antimony Japan exported 3 298,549 catties in 1886, and 3,795,610 in 1885. Great Britain receives by far the largest part of the export of fish wax (exports, 2,126,922 catties in 1886 and 3,150,122 in 1885). France and Germany receive the largest shipments, while sulphur (exports, 7,939,296 catties in 1886 and 12,466,616 the year before) is mostly sent to the United States, and a little to Australia.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

NEW METHOD FOR THE PRODUCTION OF IRON AND STEEL DIRECT FROM THE ORE.

According to a report, dated the 11th October last, of the British Vice-Consul at Moscow, a new process for producing iron and steel direct from the ore has been recently invented and patented by a Russian engineer. The Vice Consul says:—

"The whole secret of the process lies in the construction of the furnace, which is simple and inexpensive.

"It will be difficult for our ironmasters to believe that, under the new process, iron ore, after submitting it to the ordinary smelting process is taken direct from the furnace to the rolling-mill and turned into thin sheets of the finest charcoal iron, yet such is certainly the case, there being to my positive knowledge three such furnaces in this country working with perfect success.

"There can be but little doubt that the new invention will create quite a revolution in the manufacture of charcoal iron. Whether the process can be applied with equal success where coke is the fuel I cannot positively assert, as the furnaces I refer to are fired with charcoal. I am, however, assured that an experiment has been made with coke and was crowned with equal success."

DISCOVERY OF INFUSORIAL EARTH AT STAVANGER.

The following is an extract from a report by Mr. T. Michell, Her Majesty's Consul-General at Christiana, dated the 20th October last, with reference to the discovery of infusorial earth pits at Stavanger:—

"A considerable number of pits of 'infusiorial earth,' containing 85 to 95 per cent. of silica, have been discovered in the neighbourhood of Stavanger, and capital is being sought for the purpose of working those deposits, which are estimated to be capable of yielding 400,000 cubic metres of that rare product.

"It is affirmed that while similar deposits at Lyneberg, in Hanover, are mixed with sand and gravel, those now discovered are so pure in quality as to be available, for most purposes, merely after desiccation."

TRADE OF CHILI FOR THE YEAR 1886.

See *Board of Trade Journal* for November, p. 517 *et seq.*

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

APPLICATIONS.

14120 W. Bergh, London. Improvements in centrifugal apparatus for separation of fluids of different specific gravities. October 18

14153 E. N. Henwood, London. Improvements in the arrangements and construction of apparatus for injecting liquid hydrocarbons into furnaces. October 18

14169 J. J. Hicks, London. Hydrometers and saccharometers. October 18

14182 T. Kirk, Birmingham. Bye-pass cocks and valves for gas and other fluids. October 19

14209 W. H. Rusden, London. Electrical apparatus for prevention of corrosion and incrustation in steam boilers. Complete specification. October 19

14231 H. H. Lake—From O. S. Andersen, Valby. Centrifugal apparatus for separating liquids of different density or specific gravity. October 19

14251 F. Hazlett and H. McCrudden, London. Furnaces. October 20

14457 J. C. Ghest, London. The application of superheated steam to the furnaces of steam-boilers, retort-furnaces, puddling-furnaces glass-furnaces and the like, and the construction of furnaces for that purpose. October 21. Antedated April 27, under International Convention.

14500 A. Stevenson, Liverpool. Improvements in grinding or pulverising sugar, salt, and other like material, and in apparatus or machinery therefor. October 25

14539 W. L. Horne, London. Improvements in vacuum apparatus. Complete specification. October 25

14621 P. Birchall and W. Bainbridge, Longport. Nozzles, and mode of connecting same to stand or press pipes for charging filter-presses. October 27

14686 A. M. Crossley, Glasgow. Refractory or materials for lining furnaces, etc. October 28

14706 J. Nicholas and H. H. Fanshawe, London. Mode of and apparatus for carbonisation, calcination, and decomposition of organic and inorganic matter. October 28

14758 A. Schreiber, London. Smokeless furnaces. Complete specification. October 29

14931 J. J. Miller, G. J. Tupp and H. G. A. Rouse, London. Airtight furnace and retort doors and mouth-pieces. Nov. 2

15003 J. G. Hawkins and J. Barton, London. Gas retort lids, and materials and method for ensuring gas-tight joints between the lids and mouth-pieces. Complete specification. Nov. 3

15009 H. W. P. Nugent, London. Gas retort and other furnaces. Complete specification. November 3

15094 H. M. Thomas, London. Pumps for exhausting to a high state of vacuum, and for compressing air or gases to high pressures. November 5

15198 G. Pinnington, Chester. A combination of revolving pumps for raising liquids. November 8

15238 E. A. Cowper, London. Filter-presses. Complete specification. November 8

15322 H. E. Newton—From The Maschinenbau Actiengesellschaft, Austria. Filter-presses. November 9

15429 T. Newman, London. Filters. November 11

15590 W. Creswick, London. Apparatus for drying, heating, or cooling substances. Complete specification. November 14

15615 F. Goddard, Nottingham. Furnaces. November 15

15688 A. Anderson, Monkwearmouth. Appliance for consuming smoke and utilising waste heat of boilers and furnaces. November 16

15743 T. Carter, Monkwearmouth. Firebars for combined assisted and forced draughts for furnaces. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12384 J. Gilmore and J. F. Gilmore, and W. R. Clark. Steam generating apparatus. November 2

1887.

560 W. Whittaker. Mechanical stokers. October 26

686 A. Boulouse. Self-acting air valve for heating apparatus. November 2

991 W. Land. Steam generators. November 2

1914 E. Green. Fire-bars for furnaces. October 29

6287 W. Bevitt. Amalgamating apparatus. October 29

7815 T. Taylor. Consuming smoke in steam boilers. Oct. 26

12074 J. von Ehrenwerth. Regenerative gas furnaces with periodical action. October 26

II.—FUEL, GAS AND LIGHT.

APPLICATIONS.

14108 J. Mitchell, Glasgow. Improvements in the manufacture or construction of firelighters. October 18

14305 W. Weller, jun., London. Improvements in the construction of firelighters. October 21

14325 H. C. Bull & Co., Limited, and H. Clay Bull, London. Improvements in or connected with apparatus for producing and utilising "producer gas." October 21

14531 J. G. Johnson—From G. Mülheims and R. Zimmermann, France. Improvements in presses or apparatus for moulding blocks of artificial fuel. Complete specification. October 25

14589 R. H. Courtenay, Battersea. Improvements in gas apparatus, or lamps for generating gas from volatile hydrocarbons, which apparatus may also be applied to oxy-hydrogen gas incandescence and ordinary gas or other burners for lighting and heating purposes. October 26

14626 J. W. Newall, London. A method of making gas for heating purposes from tar or oil. October 27

14688 A. M. Crossley, Glasgow. Improvements in making coal briquettes or fuel blocks. October 28

14805 J. Marlow and W. Marlow, London. A fire-lighter of an improved construction. October 31

11976 R. H. Quine, Manchester. Supplying pure hot air by means of specially constructed stoves or grates to burn coal, gas, oil, or other fuel.

15067 J. C. Krayenbuhl, H. C. Peterson, and C. C. Burmeister, London. A new or improved process for the cleaning or separation of tar from ammoniacal liquor or other matters. November 4.

15082 A. Denoon, R. Jameson and A. Reid, Newcastle-on-Tyne. Utilising waste heat in coke manufacture. Nov. 5

15161 O. Knublauch, London. Improvements in production or recovery of cyanogen compounds from coal gas and other gases. Complete specification. November 7

15256 S. Pitt—From T. G. Hall, United States. Process of refining hydrocarbon oils. Complete specification. Nov. 8

15552 D. Clan Alpine Thatcher, London. A liquid fuel cartridge. November 14

15561 J. H. Glew and J. Hayes, London. Improved means and apparatus for feeding, compressing, and delivering composition firelighters. November 15

15571 G. Porter, London. Improvements relating to apparatus and fittings for enriching and burning illuminating gas. November 15

15581 J. A. Yeadon and R. Middleton, Leeds. An improved mode of moulding lumps of fuel or materials for smelting and analogous purposes, and machinery therefor. November 16

15738 J. A. Yeadon, R. Middleton and H. T. Nodin, Leeds. An improved method and appliance for cleaving blocks or briquettes of fuel, or materials for smelting and analogous purposes. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

34 J. A. Yeadon and R. Middleton. Machinery for manufacturing blocks or briquettes of fuel, etc., for smelting purposes. November 2

670 J. Broad, J. W. Broad, G. P. Broad, and H. J. Broad. Night-lights. November 16

12811 A. McKune Margerison. Firelighters. October 25

13450 T. R. Dickson. Process and apparatus for manufacturing gas, and cyanogen or its compounds. November 9

13514. P. Jensen—From J. Leede and V. D. Stockbridge. Carburettors. November 9

13627 H. Kenyon. Production of illuminating gas, ammonia, etc., and apparatus therefor. November 9

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

COMPLETE SPECIFICATION ACCEPTED.

1886.

14840 J. Young. Carbonising or distilling coal or shale. October 26

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

14464 G. Pitt, London—From A. Weinberg, Prussia. A new class of diamido compounds and azo colours produced therefrom, and the process of producing the same. October 24

14646 C. A. Bennert, London. The manufacture or production of coloured compounds or colouring materials. October 27

14820 E. Ostermayer, London. Improvements relating to the production of iodised sulpho-acids of phenols, cresol, and thymol. October 31

15154 C. D. Abel—From G. C. Zimmer, Germany. Production of yellow, red, and violet colouring matters from tetrazodiphenyl and tetrazo-ditolyle. November 7

15265 G. Thomas, Manchester—From H. Schulz, Germany. The manufacture of a certain dye matter. November 9

15374 J. Y. Johnson—From the Badische Anilin and Soda Fabrik, Germany. Improvements in the manufacture or production of red colouring matters suitable for dyeing and printing. November 10

15459 S. Forel, London. The manufacture of yellow colouring matters by the reaction of tetrazodiphenyl or tetrazoditolyl on phenol or orthocresylol. Complete specification. November 11

15647 G. Tall and W. P. Thompson, Liverpool. Improvements in or relating to the separation or manufacture of colouring matter or mordant for dyeing purposes from cotton seed or cotton-seed oil. November 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

17083 J. Y. Johnson—From the Farbenfabriken vormals Bayer & Co. Manufacture of azo dyes. November 2

1887.

875 G. Thomas—From A. Zander. Manufacture of dye matters from red sanderswood and other woods. October 22

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

14196 H. M. Girdwood, Manchester. Improvements in retting, ungumming, washing, and otherwise treating rhea, ramie, or China grass, hemp, jute, flax and certain other fibres. October 19

14477 T. A. Boyd, Glasgow. Improvements in producing variegated or fancy yarns. October 25

15178 C. Robeson, Birmingham. Improvements in and in apparatus for cleansing and scouring wool. Complete specification. November 8

15364 D. Mason, Paris—From A. Schlamm and F. à Borassard, Germany. Improvements in treating wool. November 10

15693 T. G. Lee, Manchester. An improved means for rendering woven fabrics and other goods and materials non-inflammable. November 16

COMPLETE SPECIFICATION ACCEPTED.

1887.

12709 W. Nelson and E. Bowen. Apparatus for drying wool. October 22

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

APPLICATIONS.

14092 F. R. Rothen, Manchester. Improvements in the method of and apparatus for dyeing, bleaching, impregnating and otherwise similarly treating yarn in bobbins and cops. October 18

14485 P. H. Booth, Leeds. Dyeing wool and woollen cloth and yarn, and all textile materials, either in the raw state, in process of manufacture, or manufactured, a fast and fadeless woaded green and other colours. October 25

14614 H. E. Newton—From the Actiengesellschaft für Papier und Druck Industrie Leykam Josefsthal, Austria. An improved process for bleaching jute. October 27

14813 D. Stewart and R. Walker, Glasgow. Improvements in machines for washing, soaping, or scouring piece goods. November 1

14850 J. Lodge, Huddersfield. A new treatment of worsted "tops" and other slivers of fibre for the production of an evenly mixed dyed yarn. November 1

15022 J. Lodge, Huddersfield. New or improved apparatus for dyeing worsted "tops" and slivers of fibre. November 4

15097 W. A. L. Hammersley, London. Improvements in machinery or apparatus for fulling, washing, scouring, cleaning, beating, softening, and beetling of yarns and textile fabrics. November 5

15350 M. Ashworth and R. Wild, Rochdale. Improvements in the means and method of and for the washing, scouring, boiling, and bleaching of fibres, fibrous materials, and textile fabrics, and the stripping of fibres from hides or skins, applicable for the like purposes for domestic or household use. November 10

15432 J. Grunhut, London. Improvements in dyeing. November 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15340 W. H. Turner. Machines for printing designs on paper and other material, and for decorating earthenware, china, glass, etc. October 22

1887.

174 W. Birch. Apparatus for washing, soaping, dyeing, etc., woven fabrics. November 9

VII.—ALKALIS, ACIDS AND SALTS.

APPLICATIONS.

14127 L. Mond and G. Eschellmann, Liverpool. Improvements in the manufacture of chlorine. October 18

14345 The Tyne Alkali Company, Limited, and T. Gibb, London. Improvements in the manufacture of hydrate of baryta and of strontia, and the treatment of solutions containing barium or strontium for the obtainment of compounds thereof and other products, and the utilisation of the products so obtained. October 21.

14653 W. F. R. Weldon—From A. R. Pechiney, France. Improvements in apparatus suitable for preparing oxychlorides of magnesium. October 27

14654 W. F. R. Weldon—From A. R. Pechiney, France. Improvements in apparatus suitable for use in the process of desiccating oxychloride of magnesium. October 27

14906 C. Fahlberg, London. Improvements in apparatus for he production of phosphorus trichloride. November 2

14927 L. Gueret and C. Gueret, Liverpool. New or improved process and apparatus for obtaining a continuous and determined quantity of carbonic acid or other gas. November 2

14997 J. Hanson. The treatment of alkali waste for use in the purification and deodorisation of sewage and impure waters or matters. November 3

15168 H. Senier, London. A process for the separation of zinc hydrate as a crystalline body from solution in the fixed alkali hydrates. November 7

15189 F. J. Thompson, Hertford, Cheshire. Improvements in the manufacture of salt, and generation of steam or heat, by an improved furnace and system of firing employed therein. November 8

15237 L. R. Bazin, London. A process and apparatus for conversion of phosphates into thermophosphates. November 8.

15255 G. W. Hart, London. Improvements in obtaining carbonates of soda and other products, and in apparatus suitable for this purpose. November 8

15295 A. Feldman, London. Improvements in the production of the fluorides of magnesium, of strontium, and of barium. Complete specification. November 9

15540 G. E. Davis, Manchester. Improvements in apparatus for the distillation of ammoniacal fluids. November 14

15575 C. T. J. Vautin, London. Improvements in apparatus for the separation of solutions of metallic salts from pulverised material mixed therewith. Complete specification. November 14

15687 J. Dixon, Sheffield. Improvements in the method of and apparatus for concentrating and evaporating soda lye. November 16

15770 J. F. Madocks, Andover. See Class XV.

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

13654 L. Grabau. Manufacture of fluoride of aluminium, the double fluoride of aluminium, and an alkali. October 26

16199 W. B. Giles and A. Shearer. Manufacture of phosphoric acid. November 12

1887.

13746 B. J. B. Mills—From T. B. Fogarty. Process and apparatus for producing sulphate of ammonia. November 12

13747 B. J. B. Mills—From T. B. Fogarty. Process and apparatus for producing sulphate of ammonia. November 12

VIII.—GLASS, POTTERY AND EARTHENWARE.

APPLICATIONS.

14457 J. C. Ghest. See Class I.

14619 J. Armstrong, London. Forming necks or tops on glass bottles or other articles, and appliances therefor. Oct. 27

14951 T. Minton, H. Minton-Senhouse, H. Minton Robinson, J. Clegg and J. Lea, London. A new method of printing on pottery and tiles, and apparatus therefor. November 2

15096 S. Fenn and A. Fenn, Birmingham. Improvements in fireplaces of kilns or ovens for burning bricks, pipes, terra-cotta, tiles, and other articles. Complete specification. Nov. 5

15119 D. Grant, London. A novel process of producing artistic and commercial devices in and upon glass. Nov. 11

15690 G. Wood, Leeds. Improvements in apparatus employed in the manufacture of glass. November 16

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15340 W. H. Turner. See Class VI.

15678 H. Sulley. Manufacture of glazed pavement lights. October 26

16833 W. D. Cliff. Manufacture of porcelain and metal baths. October 22

1887.

354 D. Rylands and B. Stoner. Manufacture of glass bottles, jars, etc. November 12

576 P. M. Justice. From the Société Anonyme des Manufactures de Glaces, Verres, Vitres, etc. Apparatus for handling crucibles used for melting glass. October 29

2076 J. C. Mitchell. Producing plain and ornamental designs on glass. October 29

6779 W. Lutwyche—From J. Valère. Ornamenting glass ceramic ware and metal by means of translucid and opaque enamels in relief. November 5

9292 M. F. L. Ehrlich. Producing dead gold (silver platine) decorations on china, crockeryware, glass, and enamelled metals. November 9

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

14286 J. Tennyson, London. Improved method of and devices for laying asphalte roadways, yards, and other analogous surfaces. October 22

14392 G. J. Snelus, W. Whamond, and T. Gibb, London. Improvements in the manufacture of cement. October 22

14393 G. J. Snelus, W. Whamond, and T. Gibb. Improvements in the preparation or manufacture of cements. Oct. 22

14394 G. J. Snelus, W. Whamond, and T. Gibb. An improved manufacture of cements. October 22

14551 E. B. Lee, Manchester. Improvements in the manufacture of concrete and cement fireproof building materials and parts of buildings, bridges, and other structures, safes, strong rooms, slabs, blocks, baths, tanks, and other articles, parts, and receptacles. October 26

14875 P. S. Larsen, London. Improvements in the process of crushing and screening clay. November 1

14897 P. von Krystoffovitch. An improved process for the manufacture of artificial granite. Complete specification. November 1

15028 J. Lauder, Glasgow. Improvements in artificial stone for flooring, paving, decorating, and like purposes. Nov. 4

15065 F. Ransome, London. Improvements in the manufacture of cement. November 4

15395 R. A. McGregor, London. Bricks, blocks, tiles, and any article made of clay, porcelain china, stone, terra-cotta, or other material used for building of houses, sewers, arches, etc. November 10

15596 J. W. MacKnight, London. Improvements in artificial pavement. November 15

15634 J. Gay and F. W. Wood, Northfleet. The manufacture of firebricks and other fire goods. November 15

15666 G. M. F. Layton, London. Improvements in the manufacture of cement. November 15

15733 J. W. T. Stephens, Cardiff. The manufacture of Portland, Roman, and other cements. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

424 W. White. Roads and pavements, and paving blocks therefor. November 2

11283 W. Bull. Manufacture of tiles for roofing. Nov. 5

X.—METALLURGY, ETC.

APPLICATIONS.

14159 F. L. Tirmann and H. Tirmann. See Class XXI.

14174 J. S. MacArthur, R. W. Forrest, and W. Forrest, London. Improvements in obtaining gold and silver from ores and other compounds. October 19

14221 A. B. Cunningham, London. Improvements in the reduction of lead, silver, and other metals, and apparatus therefor. October 19

14271 S. J. Evans, London. Improvements in hydraulic apparatus for preventing upsetting of converters employed in the manufacture of steel, which improvements are applicable also to hydraulic centre cranes. October 20

14311 T. C. R. Horsfield and R. Porter, London. An improved hydraulic press for mining coal and other minerals, or for other purposes requiring pressure. October 21

14356 L. Grabau, London. Improvements relating to the production of fluoride of aluminium. October 21

14371 J. Toy and S. H. Stevens, Helston. Improvements in machinery for reducing tin stuff and other partially pulverised ores to extract the metal therefrom. October 22

14451 T. Elford, G. Ackland, and R. Morgan, London. Improvements in calcining and melting copper, lead, and other ores and regulus. October 24

14452 J. A. Crawford and R. M. Black, London. Improvements in the manufacture of steel and of malleable iron. October 24

14457 J. C. Ghest, London. See Class I.

14458 F. von Ehrenworth, London. Improvements relating to the blasting of coal and other substances in mines, and to apparatus therefor. October 24

14470 M. Settle, Manchester. Improvements in or applicable to cartridges employed for blasting in mines and other places where inflammable gases are present. October 25

14482 E. B. Smith—From J. Brown, New Zealand. Improved construction or arrangement of surfaces for separating gold or other fine metal particles from quartz or earthy matters. October 25

14492 C. E. Moncrieff, Belfast. Improvements in means of raising rock salt from the mine. October 25

14515 M. Gledhill, London. An improved method of and machine for forging metals, chiefly designed for the manufacture of tubes, cylinders, shafts, and similar work. October 25

14602 C. Netts, London. Improvements in the manufacture of sodium and potassium, and in apparatus therefor. Oct. 26

14617 H. H. Lake—From A. Breden, Austria. Improvements relating to the electro-deposition of silver and nickel upon iron, steel, and other metals. October 27

14661 J. H. Bell and W. Rockcliffe, Sunderland. Improved plates for ship-building and other purposes. October 28

14687 A. M. Crossley, Glasgow. Improvements in making spiegeleisen or ferro-manganese. October 28

14700 L. A. Groth—From V. and E. Rouff, Paris. Improvements in the manufacture of chrome and its alloys. Oct. 28

14723 W. Crawford and J. Crawford, Glasgow. Improvements in shaping sheet iron, steel, or copper into vessels of various forms, and in apparatus therefor. October 29

11750 W. Lloyd, London. Improvements in the lining or fettling of puddling and other furnaces employed in the manufacture and heating of iron and steel. October 29

11784 B. C. Tilghman, Manchester. An improvement in pig iron. October 31

11792 H. J. Allison—From J. B. D'Arcy Boulton, United States. Improvements in process for casting metallic ingots. Complete specification. October 31

11793 J. E. Bott and C. H. Cousins, London. Improvements in the manufacture of cast-steel shells and projectiles, also applicable to other forms of steel castings. October 31

11803 W. Hawdon, London. Improvements in apparatus for removing molten slag, scoria, and other similar materials from furnaces. October 31

14810 W. L. Purves, London. Improvements in tempering steel. October 31

14901 C. W. Kitts, London. An improved apparatus for distributing, mixing, separating, grinding, cleaning, and amalgamating gold or other ores or tailings. November 2

15029 J. G. Beckton, Middlesbrough-on-Tees. Improvements in ingot moulds for casting steel and other metals. Nov. 4

15042 J. Tibbs, London. A new or improved covering for the bottoms of puddling furnaces. November 4

15109 A. Gutensohn, London. Improvements in apparatus for and method of pickling or cleaning the surface of iron, steel, or other metals. November 5

10199A H. C. Bull & Co. Limited, and H. Clay Bull London. Improvements relating to the production of aluminium alloys. November 10: but dated July 21, when originally filed

15185 M. Swain, Manchester. Improvements in the manufacture of hollow-ware. November 8

15245 F. J. Legge, Liverpool. Improvements in or appertaining to the manufacture of tinned or terne plates. Nov. 8

15257 W. B. Middleton, London. Method of welding steel. Complete specification. November 8

15271 M. Darnbrough and E. Darnbrough, Drighlington. Appliances to prevent the oxidation of tin, lead, or zinc, when used in tempering coating, or galvanising steel or iron wire. November 9

9389 A. C. A. Burghardt and W. J. Twining, Manchester. Improvements in the production of aluminium. Received November 11; antedated July 2, when originally filed.

15417 T. Slater and J. Laidlaw, London. An improved method of coating cast-iron or wrought-iron with other metal or alloys thereof. November 11

15425 J. Westgarth, Manchester. Improvements in and connected with galvanising and similarly coating metals. Nov. 11

15422 J. Nicholas and H. H. Fanshawe, London. A mode of and apparatus for the recovery of aluminium and other earthy metals from ores. November 11

15448 G. Trier—From E. Fischer, Denmark. Improvements in the preparation of spongy lead for use in secondary batteries or accumulators. November 11

15474 H. Hobson, Manchester. Improvements in apparatus for pulverising minerals and other hard substances and materials. November 12

15504 A. N. Contarini, London. Improvements in the process of separating precious metals from their ores, and in apparatus to be employed therein. November 12

15515 A. B. Cunningham, London. Improvements relating to the production of aluminium and aluminium alloys. November 12

15574 C. T. J. Vautin, London. Improvements in apparatus for the extraction of gold from crushed or other finely-divided auriferous material. Complete specification. November 14

15593 L. Grabau, London. Improved processes and apparatus for the production of aluminium and compounds or alloys containing the same. November 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

13183 B. H. Thwaite. Pneumatic process of manufacturing steel ingots and castings. October 22

12654 L. Grabau. See Class VII.

12682 J. R. Turnock. Machinery for coating metal sheets. October 29

13928 J. E. Baugh and C. Hinksman. Humid reduction of gold and other ores. October 29

14297 J. Nicholas. Smelting and recovering metals from ores and dross. November 5

15040 P. Rogers and J. Player. Machine for coating metal sheets with tin, lead, or other metal or alloy. October 22

16017 G. Ashworth and E. Ashworth. Apparatus for hardening and tempering steel wire and tape. November 12

16196 J. Lauer. Firing blasting charges in mines, and means therefor. October 29

1887.

271 T. B. Sharp. Manufacture of copper and other tubes and apparatus therefor. November 5

285 E. Hunt—From G. Thomson. Obtaining silver from ores, mattes, etc. November 9

331 J. Vavasseur. Steel projectiles. November 12

1751 H. H. Lake—From Count de Montgelas. Extracting aluminium from its chlorides, and apparatus therefor. Nov. 12

4581 R. H. W. Biggs. Extracting tin from iron or tin scraps, and apparatus therefor. November 5

11613 F. A. Herbetz. Cupola furnaces for smelting metals and burning malachite, dolomite, etc. October 26

11900 A. J. Shannon. Extracting antimony from its ores. November 9

12353 H. Le Neve Foster. Fire-resisting compound for forming the stoppers and nozzles used in steel-melting operations. November 5

12486 O. M. Thowless. Production of sodium and potassium, and apparatus therefor. November 5

XI.—FATS, OILS AND SOAP MANUFACTURE.

APPLICATIONS.

14187 W. Lincolne and J. Templeman, Glasgow. Improvements in the manufacture of soap. October 19

14285 J. Thomson, London. An improved mercurial antiseptic soap. October 20

14627 C. Baines and W. Thompson, London. Improved compound suitable for washing, scouring, and cleaning purposes. October 27

14693 M. J. Whibley, H. G. Whibley, and A. Williams, London. Improvements in the decolourising and deodorising of tallow, grease, and similar substances. October 28

15054 M. J. Hartung and W. Gallagher, London. An improvement in the manufacture of lubricating oils and greases. Complete specification. November 4

15134 F. Workman, H. Workman, and A. Workman, London. Improvements in presses suitable for extracting oil from linseed, and for other purposes. November 7

15314 H. Wiesinger and L. Rissmuller, London. Method of manufacturing 100 per cent. soap free of water. November 9

15490 J. W. Lord, London. Improved apparatus for expressing oil from substances. November 12

15491 J. W. Lord. Improvements in the treatment of oils for their purification. November 12

15774 C. Williams, London. Improvements relating to purifying compounds for textile materials, and to washing powders. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

14729 H. Mackay. Preparation of oils for medicinal purposes. October 29

1887.

4 R. Tervet. Apparatus for treating or purifying paraffin wax. November 2

1893 W. Hicks. Manufacture of lubricating grease. Nov. 2

XII.—PAINTS, PIGMENTS, VARNISHES AND RESINS.

APPLICATIONS.

15231 P. M. Justice—From M. B. Church, United States. Improved process of coating or painting applicable to carriage bodies and other surfaces. November 8

15320. J. Hickisson, London. Improvements in the manufacture of coloured marking ink pencils, and in the mordants or fixers to be employed therewith. November 9

15381 K. McLea and R. Punshon, London. An improved paint or varnish for iron, steel, metal, and tarpaulins. Nov. 10

15406 A. Orr, Glasgow. Improvements in making white lead. November 11

15771 F. Crane—From W. D. Field, United States. Improvements in or connected with varnishes. November 17

15772 F. Crane—From W. D. Field. Process for purifying or clarifying resins and gum resins, or solutions of the same. November 17

15773 F. Crane—From W. D. Field. Improvements in the manufacture and composition of varnish. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

16832 H. Buczkowski. Polish (soluble in water) for leather. October 22

1887.

12632 J. C. Lyman—From J. H. Lyman. Waterproof compositions or paints. November 2

13109 S. C. Rowell and J. W. Newell. Manufacture of plumbic oxide or litharge, and apparatus therefor. November 12

XIII.—TANNING, LEATHER, GLUE AND SIZE.

APPLICATIONS.

11096 H. J. Allison—From J. J. Asch, United States. Improvements in fur-dyeing ovens. Complete specification. October 18

14129 J. E. Darby and E. Blakeslee, London. Improvements in process of impregnating chamois skin with rouge. Complete specification. October 24
14699 L. A. Groth—From C. Collin and L. Benoist, Paris. Antiseptic treatment of skins before or after training. Oct. 28
15766 C. Collin, L. Benoist, B. Nicholson, and T. Palmer, London. Improvements in means for preventing the formation or development of injurious germs of animal or vegetable life, applicable to the treatment of hides or skins. Nov. 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

16617 A. Bedu. Manufacture of substances suitable for tanning. October 22
16894 J. Straiton. Apparatus for burring, cleaning, and unhairing or softening skins. October 29

XIV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

14151 H. H. Lake—From P. B. Rose, United States. An improved fertiliser. Complete specification. October 18
14701 F. H. Danchell, London. A new or improved manufacture of manure. October 28
15309 J. Davenport, London. Improvements in the manufacture of fertilisers or manuring compounds. Complete specification. November 9

XV.—SUGARS, GUMS, STARCHES, Etc.

APPLICATIONS.

14164 G. Fletcher, London. Improvements in the evaporation and concentration of sugar-cane juice and other liquids, and apparatus therefor. October 18
14801 B. E. R. Newlands, London. Improvements in means or apparatus for drying slabs of sugar, applicable for heating and cooling other articles, and for analogous operations. October 31
14883 A. Brin and L. Q. Brin, London. Improvements in the treatment of saccharine and sacchariferous matters for the purpose of decolorising, purifying, or refining them. Nov. 1
14884 A. Brin and L. Q. Brin, London. Improvements in the treatment of saccharine and sacchariferous matters for the purpose of decolorising, purifying, or refining them. Nov. 1
15770 J. F. Maddocks, Andover. The direct steam boiling of acid solutions generally, and the inversion of cane sugar in particular. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15115 J. Baker, J. A. Baker, W. K. Baker, and G. S. Baker. Machines for manufacturing sugar wafers, etc. October 22
16827 H. Vivien. Apparatus for the manufacture of refined sugar, glucose starch, etc. October 26

1887.

165 C. D. Abel—From Pfeifer and Langen. Method for extracting foreign substances (raffinose, etc.) from sugar solutions by means of lead. November 5
12831 N. Tscherikowski. Producing refined sugar from raw sugar. November 12

XVI.—BREWING, WINES and SPIRITS.

APPLICATIONS.

14189 D. Mason—From V. d'Ostachiewicz and L. de Gerlicz, France. Improvements in the process and use of substances for the production of alcoholic fermentation. October 25
14518 J. F. Henderson, London. Improvements in or applicable to the manufacture of wine. October 25
14737 T. G. Bowick, Harpenden. An improved process and apparatus for purifying alcohols by means of hydrocarbons. Complete specification. October 29

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

54 P. Weinig. Malt germinating apparatus. October 22
521 E. Beanes. Treatment of wines of the port and claret class. October 26

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

APPLICATIONS.

A.—Chemistry of Foods.

14095 H. J. Allison—From The De la Vergne Refrigerating Machine Co. Limited, United States. An improved process for refrigerating by compression and expansion of gases, when such gases are compressed in contact with or in presence of lubricating liquids. Complete specification. October 18
14378 S. Puplett and J. L. Rigg, Knowle. Improvements in apparatus for mechanical refrigeration, and for the artificial production of ice. October 22
14410 L. Sterne—From J. C. de la Vergne, United States. Improvements in the manufacture of pure ice, and apparatus therefor. Complete specification. October 24
14527 J. F. Henderson, London. Improved compounds of coffee and cocoa. October 25
14711 S. M. Macrory, London. Improvements in the treatment of vats, and obtaining a new product therefrom. Oct. 28
14744 E. Scherff and C. Drenckham, London. An improved process for condensing milk and other fluids containing proteine, and preserving the same in glass or other hermetically closed vessels. Complete specification. October 29
14945 N. P. M. Tronson, London. Manufacture of a food for animals from wood. November 2
15502 A. Horn, London. Improved means of applying saccharine as a preserving and sweetening agent Nov. 12
15578 J. Hofmann, London. Improvements in the manufacture of brown bread. November 14

B.—Sanitary Chemistry.

14364 J. Greenwood, Keighley. Improvements in valves applicable for the outlets of sewage tanks, barrels, and the like. October 22
14656 T. Glennie, Glasgow. A new system of sewage disposal. October 28
14857 A. Engle, London. A furnace for and process of burning wet and offensive substances. Complete specification. November 1
14982 F. A. Hillé, London. Improvements in treating sewage, and in liquid disinfectants used for that purpose. November 3
15381 E. Hermite, E. J. Paterson, and C. F. Cooper, London. A process for disinfecting impure liquids. November 10
15385 E. Hermite, E. J. Paterson, and C. F. Cooper. Apparatus for disinfecting impure liquids by electrolytic action. November 10
15431 W. C. Roberts, Putney. An improved construction or arrangement for chemically charging water-closets to prevent the formation of noxious gases, and to destroy offensive smells arising from soil pipes, drains, etc. November 11
15519 S. Holman, London. Improvements in means or appliances for exhausting or consuming foul air or gases from sewers, or other places containing foul air or gases, and for effecting ventilation of the same; applicable also for heating purposes. November 12

C.—Disinfectants.

14861 W. B. Giles and A. Shearer, Stratford. The manufacture and application of new antiseptic and disinfectant substances. November 1
15564 A. Boake, F. G. A. Roberts, A. Shearer, and W. B. Giles, London. An improved manufacture or preparation of antiseptics. November 14
15668 W. J. Cooper, London. An improved antiseptic or disinfectant. November 15

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods,

1887.

4063 W. L. Wise—From C. A. Wahlin, A. Forssell, and F. L. Enquist. Treatment of milk. October 29

B.—Sanitary Chemistry.

1887.

13781 W. Mann. Refuse burners. November 12

C.—Disinfectants.

1886.

16834 F. H. Weber. Candles for fumigating or deodorising. October 22

1887.

276 C. T. Kingzett. Solutions for use as antiseptics, disinfectants, deodorants, oxidants, and general sanitary reagents. October 26
381 J. S. Stevenson, M.P., and J. G. Tatters. An improved disinfectant and oxidising agent. November 9
402 H. Schlichter. Platinum lamps for deodorising and disinfecting. November 9
451 R. V. Tuson. Production of powders for disinfecting and deodorising. November 9

XVIII.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

14107 N. G. Thompson, London. Continuous current commutatorless dynamos. October 18

14222 A. S. Elmore, London. Improvements in the electrolysis of aqueous solutions. October 19

14259 C. Hall and H. Binks, London. Improvements in the application of primary batteries for electric signals, telephones, lights, or other purposes. October 20

14270 B. J. B. Mills—From E. Emerson, United States. Improvements in means or apparatus to be employed in the production of sheet copper by electro deposition. October 20

14273 A. J. Littleton, Sydenham. Separating the plates of secondary batteries. October 20

14426 Sir C. S. Forbes, Bart., London. Producing voltaic electricity by means of a cell of which the positive element consists of an amalgam of either sodium or potassium or of both. October 21

14461 A. Stetson, London. Improvements in electric accumulators or secondary batteries. October 24

14622 E. W. Vaughton, Birmingham. An improved electric accumulator. October 27

14729 W. H. Douglas, Birmingham. An improved meter for measuring electrical currents. October 29

14901 C. R. Goodwin, Paris. Improvement in electric batteries. Complete specification. November 2

14954 W. Terrill, London. Improvements in apparatus to be used in the deposition or treatment of metals by the electrolytic process. November 2

15063 D. Skrivanow, London. Improvements in galvanic batteries. November 4

15141 A. F. St. George and C. R. Boune, London. Improvements in galvanic batteries. November 7

15259 T. J. Jones, London. An improvement in voltaic batteries. November 8

15321 J. Pitkio, London. Improvements in electrical storage batteries. November 9

15323 A. Schanschieff, Gipsy Hill. Improvements in galvanic batteries. November 9

15385 E. Hermite, E. J. Paterson, and C. F. Cooper. See Class XVII. (B.)

15392 H. J. Haddan—From B. Scheithauer, Germany. Improvements in primary batteries. November 10

15532 S. Joyce, London. Electric explosives. November 14

15555 W. M. Mordey, London. Improvements in and pertaining to electric motors and their application for charging secondary batteries or accumulators. November 14

15588 J. Y. Johnson—From W. C. Recknicwski, France. Improvements in dynamo-electric machines. Complete specification. November 14.

15730 J. V. Sherrin, Ramsgate. Improvements in galvanic batteries. Complete specification. November 16

15751 W. J. S. Barber-Starkey, Manchester. Improvements in the electrolytes of secondary voltaic batteries. Nov. 17

15760 W. Webster, jun., London. Improvements in the electrolytic treatment of sewage and sea-water for the production of certain products therefrom, and apparatus therefor. November 17

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

15831 F. E. Elmore. Apparatus for the deposition or obtainment of metals by electrolysis. November 5

1887.

114 W. A. Leipner. Dynamo-electric and electro-dynamic machines November 12

4303 W. Main. Secondary and other batteries. October 22

13722 C. E. Ponder, J. McGregor, and P. Harris. Secondary batteries. November 12.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

14521 C. J. Richardson and R. Squire, London. Improvements in apparatus for the manufacture of paper. October 25

14733 J. Jameson, Newcastle-on-Tyne. Improvements in the preparation of safety paper, affording protection against erasure or other alteration. October 29

15386 C. Morfit, London. Improvements in the manufacture of paper. November 10

15419 C. Morfit, London. Improvements in the manufacture of paper. November 11

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

14614 D. Allport. Incorporating wire with paper, paper-pulp, wood-pulp, etc. November 9

1887.

8391 J. Craig—From C. H. Hanbold. Manufacture of paper suitable for use for calender bowls. October 22

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

APPLICATIONS.

14459 A. Brunn, London. Improvements relating to the production of peptone and maltose or maltose substances. October 24

14689 W. Stevenson and R. Howell, London. Improvements in the manufacture of aerated beverages and syrups and essences for carbonating or flavouring purposes. October 28

15587 C. D. Abel—From W. Roser, Germany. Improvements in the production of alkaloids. November 11

XXI.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

14159 F. L. Tirmann and H. Tirmann, London. Improved percussion fuses for shooting and blasting purposes, especially applicable for working in mines infected with fire-damp. October 18

14390 R. Morris, London. An electric firing fuse or primer. October 22

14470 M. Settle. See Class X.

15532 S. Joyce, jun., London. Electric explosives. Nov. 14

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

391 W. Bickford-Smith and G. J. Smith. Means of igniting fuses without exposing flame or sparks. November 9

393 W. Bickford-Smith and G. J. Smith. Means of igniting fuses without exposing flame or sparks. November 9

11658 E. Edwards—From R. Sjöberg. Explosives. Nov. 2

XXII.—ANALYTICAL CHEMISTRY.

APPLICATION.

15667 B. Nieholson and T. Palmer—From C. Collin and L. Benoist, France. A process for testing or estimating the strength of solutions of tannin. November 15

Printed and Published by Emmott & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.
London Office, for the Sale of Copies and Receipt of Subscriptions: 6, York Street, Covent Garden

THE JOURNAL
OF THE
Society of Chemical Industry:
A MONTHLY RECORD
FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 12.—Vol. VI. DECEMBER 31, 1887. Non-Members 30/- per annum; Members 21/- per Set; Single Copies 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S. ..	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S. ..	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.

COUNCIL FOR YEAR ENDING JULY, 1888.

President: Prof. James Dewar, F.R.S.

Vice-Presidents:

Prof. F. Clowes, D.Sc.
Sir J. Neilson Cuthbertson.
David Howard.
Dr. Ferdinand Hurter.
Ivan Levinstein.
E. K. Muspratt.
Dr. W. H. Perkin, F.R.S.
Sir H. E. Roscoe, M.P., F.R.S.
John Spiller.
Prof. W. A. Tilden, F.R.S.
John Williams.
Philip J. Worsley.

Ordinary Members of Council:

John Calderwood, F.R.S.E.
Eustace Carey.
R. Forbes Carpenter.
James Duncan.
Dr. John Evans, F.R.S.
S. H. Johnson.
John Pattinson.
B. S. Proctor.
F. J. Rowan.
Dr. Edwd. Schunck, F.R.S.
T. W. Stuart.
Lewis T. Wright.

With Sixteen Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Ludwig Mond, 20, Avenue Road, Regent's Park, N.W.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

NOTICES.

Notice is hereby given that the numbers for January 1882, 1883, and 1886, and February, 1886, are exhausted, and no orders for those copies can be executed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January, 1882, at the price of 5s. each. Members possessing odd copies of this number are particularly requested to communicate at once with Mr. Cresswell.

Authors of communications read before the Society or any of its Local Sections are requested to take notice that, under Bye-Law 43, they cannot receive the prescribed 50 copies of their communications unless they comply with the condition laid down in that Bye-Law—viz., that they give notice of their desire to receive such copies upon their manuscript before sending it to the Editor. Mention should also be made as to whether the Discussion is to be included in the reprint.

Members are requested to note that the subscription of 25s. for 1888 falls due on the 1st January. Cheques and orders should be made payable to the Honorary Treasurer, Mr. E. Rider Cook, and forwarded either to him, at Bow, or to the General Secretary. Until payment is made members are not entitled to the Society's Proceedings, under Rule 29 of the Bye-Laws.

CHANGES OF ADDRESS.

Jno. Anderson, l/o Glasgow; Workington Ironworks, Workington, Cumberland.

W. H. Aubrey, l/o St. John's; 121, Burrage Road, Plumstead, S.E.

G. Christopher, l/o Clapham; 5, Shoe Lane, E.C. (for Journals) and 6, Barrow Road, Streatham Common, S.W.

Dugald Clerk; Journals to Driffold Villa, Sutton Coldfield, near Birmingham.

G. Gilmour, l/o Fifeshire; c/o Dublin Whisky Distillery Co., Jones Road, Dublin.

W. J. Hall, l/o Venezuela; c/o Wm. Lucock, Hudson Street, Tyne Dock.

R. Lucas,, l/o Manchester; Mainzerstrasse, 8, Wiesbaden, Germany.

J. A. Macfarlane, l/o Barcelona; c/o La Compania Unida, Guanjuato, Mexico.

W. M. Miller; Journals to Laboratory, Pln. Tuschen den Vrienden, Demerara, W. Indies.

E. Kennard Mitting; Journals to 273, Clinton Street, Brooklyn, N.Y., U.S.A.

Dr. B. Mohr; Journals to 69a, Parliament Hill, Hampstead, N.W.

H. E. Taylor, l/o Langdale Road; 4a, Brand Street, Greenwich, S.E.

Harold Wager; Journal to 2, Phené Street, Chelsea, S.W.

C. Greville Williams, l/o Wandsworth Common; 4, Queen Anne's Terrace, Schubert Road, Putney, S.W.

Jas. Wood, l/o Whalley; Foxhill Bank Printworks, Church, near Accrington,

CHANGES OF ADDRESS REQUIRED.

T. S. Boulton: l o Mountford House, Barnsbury Square, N.
Dr. J. M. Morrison: l o Beulah Hill, Upper Norwood, S.E.

LIST OF MEMBERS ELECTED, 16th DECEMBER, 1887.

H. Broadbent, c o Goodall, Backhouse & Co., Sovereign Street, Leeds, chemist

F. H. Perry Coste, Laboratory, 17, Tower Street, London, E.C., analytical chemist.

James Dale, 182, Lordship Road, Stoke Newington, N., coppersmith.

Chas. F. Mabery, Case School of Applied Science, Cleveland, Ohio, U.S.A., Professor of chemistry.

Chas. C. Moore, 125, Chester Road, Hartford, Cheshire, chemist.

Chas. Oxland, Greystoke, Palace Park Road, Sydenham, S.E., mining engineer and metallurgist.

Frank A. Roberts, Messrs. Roberts, Dale & Co., Warrington, chemical manufacturer.

George W. Slatter, Saltaire Works, Shipley, Yorkshire, analytical chemist.

Thos. Snape, Phœnix Alkali Works, Widnes, alkali manufacturer.

Oscar J. Steinhart, 47, Earl's Court Square, South Kensington, S.W., Ph.D., chemist.

Death.

R. R. Kelly, l o 3, Pall Mall East, London, S.W.

Communication.

REPORT ON SECTION III. OF THE MANCHESTER ROYAL JUBILEE EXHIBITION:

THE CHEMICAL AND ALLIED INDUSTRIES.

BY WATSON SMITH,

Lecturer in Chemical Technology in the Victoria University, etc.

(Continued from p. 701.)

GROUP X.—FATS, OILS, AND SOAPS.

Joseph Crosfield & Sons, Warrington (No. 838).—Toilet and household soaps, and more especially a Turkish temple, entirely built of cakes and blocks of soap. The structure was so arranged that whilst in it elegance and artistic effect were combined, yet every variety and colour of soap was brought in and exhibited. A silent hand stamping machine was shown in operation, producing small tablets of the speciality of the firm, the "Perfection" soap, in which it is claimed that no free alkali and only very little free fat are present.

Joshua Margerison & Co., White Windsor Soap Works, Preston (No. 842).—Besides samples of various soaps are elegant designs in the speciality of the firm—viz., a scented white curd soap.

William Brown, Victoria Soap Co., Limited, 47, Oldham Road, Manchester (No. 844).—Specimens of soaps for silk throwing, spinning and dyeing, cotton sizing and feeding; also prepared soap for cops. Fulling and scouring soaps.

T. B. Rowe & Co., Thames Soap Works, Brentford, London (No. 845).—The exhibits of this firm consist of a variety of soaps for manufacturing purposes, as follows:—

(*a*) *White Oil Soap*, a neutral emollient soap used by China silk throwsters, and manufacturers of machine-made writing papers.

(*b*) *Refined Curd Soap*, used by white silk throwsters and cotton bleachers.

(*c*) *Mottled Soap.*—This is used by calico printers, by clothiers for milling and scouring, and for domestic and laundry purposes.

(*d*) *Bengal Yellow Soap*, used for "boiling off" Bengal silks, and for softening and glossing them.

(*e*) *Brown Oil Soap*, used by general silk dyers as an addition to certain dye baths.

Since the duty on soap was abolished in 1852 there have been no means of estimating accurately the amount of soap annually produced, but it was calculated that in 1881 the quantity had risen to 225,000 tons.

James Alexander & Co., 18, Paradise Street, Lambeth, London (No. 846).—Savon Hamamelis Virginica, or Hazel soap. (See this Journal, 1885, p. 563.)

Gray, Smith & Bennett, Rockingham Soap and Starch Works, Wath-upon-Dearne, Yorkshire (No. 847).—Household soaps, toilet soaps, soft soap, dry soap, milling and scouring soaps, starch, and various chemicals, tallow, etc., used in the manufacture of these articles, their annual production amounting to about 1500 tons.

David Shaw & Co., 35, Market Street, Manchester (No. 858).—Machinery oils suitable for cotton and woollen industries, some of which are known as *stainless oils*. *Cylinder oils* are shown in the various stages of manufacture, from a dark green to a pure white. *Prepared tallow* for engines, and oils suitable for railway and colliery lubrication, *oleine*, *cloth*, *wool*, and *soap oils*, and the tallows and fats from which they are made. Samples of yarns spun, and scoured with these oils are also shown. A variety of greases, showing the various stages of distillation and refining. *Lanolin*, made from the grease recovered from wool scouring liquors, *olive*, *fish*, *animal*, and *seed oils*, *chemical manures*, *paraffin wax*, and a bust in stearin made from tallow and palm oil, are also exhibited.

A. B. Fleming & Co., Limited, Caroline Park, Edinburgh; and 67, Piccadilly, Manchester (No. 859).—Patent solidified oil and lubricators, spindle, loom and engine oils, cylinder and valve oils, Russian and American colliery greases. The new mineral fibre, known as *agalite*, both in its native rock-form and ground. The special features of this exhibit are the solidified oil and the agalite. The first of these is a lubricant intended to replace tallow and suet. Tallow often contains acid and suet always leaves a residue of membranous matter, and both these lubricants act injuriously on india-rubber valves. It is claimed that the solidified oil has none of these drawbacks. *Agalite* is a fibrous silicate of magnesia, similar to asbestos. It is obtained from America in the form of a powder, which under the microscope is seen to consist of small elastic fibres. It is used by paper-makers as a "loading" for paper instead of China clay, and for this purpose from 6000 to 7000 tons are consumed annually.

John Sandeman, Ruchill Oil Works, Maryhill, Glasgow (No. 860).—Specimens of greases prepared from mineral oils, for use in collieries, and for carts, cogwheels, etc. Rosin oils, used for printing ink, jute-batching, etc. Siccative, used as substitute for linseed oil in paints and varnishes. Rosin spirits and rosin pitch.

Edwin Washington Wollaston, 12, Dutton Street, Manchester (No. 867).—This firm exhibits lubricating and burning oils, as enumerated below. (1.) Oils and tallow; oils for all kinds of machinery. These oils are stated to be free from acidity and mucilage. (2.) Burning oils, for lamps of all kinds; colza oil, refined rape oil, cotton seed oil, colliery lamp oil, marine lamp oil, brown rape oil, seal oil, petroleum oil. (3.) Various oils for machinery, calico printers, dyers and finishers, woollen mills, bleachers, painters, etc., etc. The oil trade comprises a great variety of productions from animal, vegetable and mineral sources. In Manchester and the district within 30 miles, the chief sale of oil is for machinery, spindles, looms, and engines. For this purpose mineral or hydrocarbon oils have largely taken the place of sperm, animal, and other oils, and the average price has been reduced from about 8s. per gallon to 1s. 6d. per gallon.

The superiority of mineral oils as lubricants for machinery rests on the fact that being hydrocarbons, and having a somewhat inert character they do not decompose and give rise to corrosive and sticky products under the action of steam, heat, and the oxygen of the air, as do the ordinary vegetable and animal oils: the latter are of course composed of glycerol and fatty acids, and under the influences mentioned oxidise and produce sticky resinous substances, or they decompose more or less readily according to their origin and quality into the component parts referred to. The liberated fatty acids act very energetically upon iron, especially under the influence of steam, hence in ocean steamers mineral oil has practically displaced tallow as a lubricant for the cylinders of the steam engine. The chief point to be attended to is the selection of a mineral oil of such viscosity that it is entirely adapted to the light or heavy character of the machinery and its bearings. So many improvements have been effected in the distillation, etc., of mineral oils in recent years, that it has now become possible to obtain an oil suitable for every possible purpose of lubrication. The average prices given below, for the various oils and tallow in 1870, 1880 and at the present time, show a great reduction in value:—

	1870			1880			1887		
	s.	d.		s.	d.		s.	d.	
Olive oil	54	0	per cwt.	44	6	per cwt.	36	0	per cwt.
Rape oil	46	6	,,	32	0	,,	21	0	,,
Linseed oil	33	6	,,	28	6	,,	22	0	,,
Cotton seed oil	35	0	,,	28	0	,,	21	0	,,
Palm oil	38	6	,,	31	0	,,	20	0	,,
Cocoa-nut oil	47	6	,,	38	6	,,	38	0	,,
P. T. C. Tallow	47	0	,,	43	0	,,	32	0	,,
Mineral oil	15	0	,,	10	0	,,	6	0	,,
Lard oil	6	0	per gall.	3	3	per gall.	3	4	per gall.
Sperm oil	7	0	,,	4	9	,,	3	0	,,

Joseph Kershaw & Co., Hollinwood, near Manchester (No. 869).—Samples of non-conducting composition for coating steam boilers, steam pipes, and all steam heated surfaces, also a variety of greases, soaps, lubricants, and paints, etc. Thirty years ago steam heated surfaces were usually left bare, and nothing was adopted as a non-conducting coating to prevent loss of heat. Later, well-mixed mortar and hair was used, then laths and a second coating of the mortar and hair were applied, and finally cloth was put over all and painted. At the present day there is a large number of non-conducting compositions in the market, and this firm particularly claims for its composition, that it is very hard, does not shrink, and is not destroyed by the continual heat to which it is subjected.

Wm. Gossage & Sons, Widnes, Lancashire (No. 872).—A most elegantly constructed pavilion containing large specimens in illustration of the history, chemistry, and manufacture of ordinary English soaps. The chemical substances employed in soap-making in former times and as now used. Palm plant, with fruit from which palm oil, as imported from Africa, is made. Raw palm oil as imported. Cocoa-nuts, in fibre and divested of fibre. Coprah, the dried fleshy part of the cocoa-nut, from which cocoa-nut oil is expressed. Palm nuts and palm kernels from which palm-kernel oil is made. Cotton seeds from Egypt, from which cotton oil is produced. Kelp weed. Kelp salts, as used by soap makers before the invention of Le Blanc revolutionised the soda manufacture of the earlier period. Soda ash. Caustic soda and soda crystals. Spent lye, waste liquor from soap making, the largest source of glycerin. Crude glycerin. Pure glycerin, fit for dynamite making. Imitation sample of nitro-glycerin and cases (empty) in which dynamite is usually packed to form dynamite cartridges. Silicates of soda and potash, both solid and liquid. Besides the employment of silicate of soda (water glass) in soap making, it is also used largely in the manufacture of artificial stone, and in calico printing The calico with which this court was draped had been printed by a process in which silicate of soda served as "fixing agent" for the alumina of the alumina mordant employed.

Lever Brothers, Sunlight Soap Works, Warrington (No. 873).—The exhibit of this firm consists of samples of their soap, known as the "sunlight soap." They show the "stamping" process by which the soap tablets are produced, also a series of illustrations of the methods of using the soap, and a complete model to scale in fibrous plaster of the "Sunlight" Soap Works at Warrington. The whole was enclosed in a beautiful pavilion resembling a Turkish Mosque, and adjoining that of Messrs. Gossage & Sons, which it almost rivalled in elegance. It is claimed for the "sunlight" soap, that it is perfectly saponified and only contains a trace of free alkali.

In this Section the department of soaps, oils, greases and fats, was most largely represented, besides those mentioned the following firms also exhibited:—N. Kilvert & Sons, Henry Shaw & Co., David Thom & Co., William Brown, Chiswick Soap Company, Hazlehurst & Sons, J. C Paton & Son, Geldart & Co., Roy & Co., Bignall & Co., Smith & Forrest, Robert Brown & Co., The Health Soap Company, George & George W. Skelton, George Fairclough, Senior & Brooks, Limited, Colledge Roy & Co., Broadbent & Son, J. Veitch Wilson, Halliday & Co., W. H. Samuel & Co., James Light & Son, and Robert Oliver & Co.

GROUP XI.—TANNING, LEATHER, GLUE, GELATIN, ETC.

William Walker & Sons, Rose Hill and Bark Street Tanneries, Bolton (No. 874).—This firm exhibits English sole leather (bends), shoulders, bellies, and the curried goods known as English strap-butts, welt-shoulders, and clog-butts. The art of manufacturing sole leather, and some species of upper leather, has been known from ancient times, but it is only during the last half-century that tanning has become a science, and that the value of chemistry has been appreciated by the tanner. The manufacture of strap-butts is a growth of the present century, and it has naturally developed with the increased application of machinery throughout the world, until now it may be estimated that there are manufactured from English strap-butts alone upwards of from 35 to 40 million feet of belting per annum. The manufacture of "clog-butts" is mainly confined to this country, and is not an increasing industry. Probably less than a million pairs of clogs are made annually in England, and these are made entirely from English leather. The number of hides and skins imported into this country for English consumption may be roughly estimated at about 9,000,000 per annum, the bulk of which come from South America, the Cape, Australia, Brazil, Madagascar, and the West Indies. With regard to English hides, if we take as a basis the amount of beef consumed in Lancashire, the supply of hides will be about 195,000 to every half-million inhabitants. This would mean a total of about 10,000,000 English hides per annum, and about 1,000,000 calf skins. The value of these hides (in all about 20,000,000) is probably 15 to 18 millions sterling, and this value, after the cost of tanning, and perhaps currying has been added, will probably be increased to something between 30 and 40 millions sterling. (For statistics of exports and imports, see description of exhibit 878.) The chief tanning agents used in England are, oak bark, stripped in English and Belgian forests, valonia from Smyrna, myrabolams from the East Indies, divi divi, Mimosa bark, hemlock, and other extracts used in smaller quantities. The staple agents used in currying are cod oil from Newfoundland, and tallow melted in England or imported from Russia.

Henry Parkinson & Co., Latchford, near Warrington (No. 875).—Specimens of heavy and light sole and in-sole leathers, also army, hydraulic, and other machinery leathers. The chief characteristic of these materials is their fineness of texture and compactness of pattern, and these qualities are attained by special preparation. The ordinary sole leather is tanned for nine months in oak-bark liquors, and three months in strong valonia liquors, to give solidity. The leather for army and hydraulic purposes is continued six months longer in the valonia liquors. The "offal" or in-soling is tanned for a period of six months only.

James Taylor & Sons, 27, 29 and 31, Union Square, Bury, Lancashire (No. 878).—Specimens of closely-rounded English bends exhibited, weighing 10lb.—19lb., made from English hides and tanned with oak bark and valonia, also "ranges" cut from the above and specially adapted for slipper and shoe work. Shoulders for sewing, pegging, or riveting, in-soles, welt-shoulders, and oak bark tanned, hand-shaved, shoe-butts matured in grease before finishing. Black-grained butts for shooting boots, brown-grained for army purposes, and clog-butts for both whole-backed and seam-backed clogs. East India kip-butts of all weights and classes. Black and brown bellies and black shoulders for slippers and boots. Harness hides and backs, black and brown. The following materials employed in tanning are also shown:—*Tanning Extracts:* Clarified oak, myrabolam, sumac, valonia, larch, and divi divi extracts. *Ground Tanning Materials:* Extra best Palermo sumac, fine ground myrabolams. *Raw Tanning Materials:* Sumac, divi divi, myrabolams, and valonia.

IMPORTS INTO THE UNITED KINGDOM OF ARTICLES CONNECTED WITH THE LEATHER TRADES DURING THE YEAR ENDING DECEMBER 1, 1886, WERE:—

Hides (dry)	732,578 cwt.
,, (salted)	518,542 ,,
Leather	76,633,037 lb.
,, value	£5 462,966
Boots and shoes dozen pairs	104,489

EXPORTS FROM THE UNITED KINGDOM DURING THE YEAR ENDING DECEMBER 1, 1886:—

Hides (dry)	516,096 cwt.
,, (salted)	118,427 ,,

British Manufacture.

Leather unwrought	155,050 cwt.
Declared value	£1,380,231
Leather wrought, and boots and shoes, declared value	£1,829,549
Saddlery and harness, declared value	£382,819

Gridley & Co, Bishopsgate Avenue, London (No. 876).—This firm exhibits Russian isinglass. Brazil isinglass in similar stages. Isinglass of every description, in crude state, from Penang, Bombay, Hudson's Bay, West Indies, Saigon, Singapore, and China; also the same kind in their manufactured condition. The trade in isinglass, though considerable in itself, is small compared with many other fish industries. Isinglass consists of the dried swimming-bladder of different fishes. The bladders vary much in shape, according to their origin, and they are prepared for the market in various ways. Some are simply dried while slightly distended, forming pipe isinglass. When there are natural openings in these tubes they are called purses. When the swimming-bladders are split open, flattened, and dried, they are known as leaf isinglass. Other things being equal the value of a sample is determined by the amount of impurities present. These impurities are ordinary dirt, mucus naturally present inside the bladder, technically called grease, and blood-stains. If the bladders were hung up to dry with the orifice downwards, the mucus could be drained off; but usually the fishermen fear the reduction in weight, and take care to retain all they can. It is necessary to insist on having the bladders slit up and rinsed clean as soon as they are removed from the fish. This would so much increase the value of the product that the extra labour would be very profitable. Blood-stains cannot be removed without injuring the quality. If any process could be devised effectual for this purpose, a valuable discovery would be made. The chief places of production are Russia, Siberia and Hudson's Bay, Brazil, West Indies, Penang, Bombay, Manilla, this being approximately the order of their importance. All Russian and Siberian is known as Russian, the more frequent varieties being "Beluga leaf," the finest in the market, obtained from a species of sturgeon; Astrakhan leaf; Saliansky leaf and book; and Samovy leaf and book. The fish yielding them inhabit the great rivers and fresh-water lakes. They are caught during the winter, and the bladders removed and dried in various forms. The winter catch is collected at the great fair at Nijni-Novgorod, and is there bought by brokers and merchants from St. Petersburg. Some trade is done in Hamburg, but the varieties there sold are not what we know as Russian. When the ice breaks up the isinglass is shipped by steamer as quickly as possible, mostly to the London Docks, on account of the isinglass merchants there. The end of June and the beginning of July is the season when the winter's produce reaches this country. The Brazil, Penang, Bombay, and Manilla products are imported at all periods of the year, generally packed in cases, varying in weight. Original cases of Penang isinglass weigh about 3cwt.; Manilla, about 2cwt.; Brazilian, about 2cwt. 3qrs. The uses of isinglass are not very varied. The largest quantity is used by brewers and wine merchants for clarifying their goods. This property is extraordinary, for gelatin, which seems chemically the same thing as isinglass, does not possess it. One theory is that the tenacious mucilage shaken with the liquid gradually settles to the bottom, entangling all floating particles as it sinks. Another suggestion is that a very delicate fibrous network remains after the isinglass is dissolved, and entangles the particles in the way the mucilage is supposed to act. Many varieties of isinglass, generally the lower brands, are used for this purpose. Some brewers use it in the natural state, others prefer it manufactured into a fine or wide strip, which dissolves quicker, and suffers no waste. At present, Penang is the favourite kind. Russian long-staple isinglass is used only by the Worcestershire farmers for clarifying their cider. In spite of its costliness, Scotch brewers prefer Russian leaf. The use of Samovy isinglass was formerly universal among the Irish brewers, and much is still sent to Dublin; but other varieties have partly taken its place. It is a Russian kind, obtained from the bladders of the *som* fish. Its name is the adjective form of the noun *som*. It is used only by brewers. Russian isinglass is also shipped to Madeira for use in clarifying wines. A good deal of various kinds is used in this country by wine merchants. For clarifying purposes the isinglass is "cut" or dissolved in acid, sulphurous acid being used by brewers, as it tends to preserve the beer. When reduced to the right consistence, a little is placed in each cask before sending it out for consumption. Sole skins are the only substitute used for isinglass. They can only be had in winter, the supply is uncertain, and they have not the strength of the Penang varieties. Next to the brewer's demand comes that of the cook, who uses it for making jellies, thickening soup, and stiffening jams. For this purpose best Russian takes the highest position, owing to the superior strength and nourishing properties. Isinglass being the purest natural form of gelatin, a very pure article, artificially prepared without the use of acids or other chemicals, has long been known in the market as patent isinglass. It does not possess the clarifying power of the natural article, but is equally useful for cooking. There seem to be only six isinglass cutters in England, all being domiciled in London. The sorted isinglass is very hard and tough, very difficult to bend or manipulate. It is soaked till it becomes a little pliable, and is then trimmed. Sometimes it is just pressed by hand on a board with a rounded surface, at others, it is run once between strong rollers to flatten it a little, and make the dark and dirty spots accessible to the knife, the top of the roller being used to bend the pieces on. The cuttings are sold separately as an inferior grade. The next process is that of rolling. Very hard steel rollers, powerful and accurately adjusted, are used. They are capable of exerting a pressure of 100 tons. Two are employed, the first to bring the isinglass to a uniform thickness, and the smaller ones kept cool by a current of water running through them, to reduce it to little more than the thickness of writing paper. It is very curious to see the thick, tough pieces gradually spreading out under the rollers, and folded and rolled like puff-pastry till the separate pieces so unite that no joint can be seen, and the mass is reduced, under the coarse rollers, to what looks like semi-transparent millboard. From the finer rollers it comes in a beautifully-transparent ribbon, many yards to the pound, "shot" like watered silk, in parallel lines about an inch broad. It is now hung up to dry in a separate room, the drying being an operation of considerable nicety. When sufficiently dried, it is stored till wanted for cutting, or it is sold as ribbon-isinglass to all who prefer this form. The machines for cutting are well and accurately made, and are so adjusted that they slice pieces off a sheet of paper without stirring or bending it in the least. For the "fine-cut" isinglass in which chemists are interested, these machines are run a great speed, 2000 to 2500 revolutions, making 10,000 to 12,000 cuts in a minute. It takes an hour to cut 5lb. or 6lb., so that each pound would contain 100,000 to 125,000 separate fibres if none of them were broken. The actual number must be very much greater.

J. M. Collett & Co., High Orchard Works, Gloucester (No. 823).—Already noticed on page 701, under Group IX., alkalis, acids, and salts. Besides being an exhibition of sulphites and bisulphites, is also an exhibition of isinglass from Russia, Siberia, Brazil, Penang, Bombay, Kurrachee, and Manilla.

Thomas R. B. Bindley & Son, Smethwick, near Birmingham (No. 877).—Sample cakes of gelatins and glues. Samples of size and grease. Specimens of articles of different trades in which these goods are consumed. Raw materials from which manufactured, and the refuse products.

GROUP XII.—INDIARUBBER, GUTTA-PERCHA, ETC.

Chas. Macintosh & Co., Cambridge Street, Manchester (No. 885).—This exhibit has been divided into two parts, one of which is devoted to the origin of indiarubber and the various materials used in its manufacture, and the other to the processes of manufacture of finished articles. Probably no exhibit illustrating the indiarubber industry has ever before been shown of so complete a kind.

The articles exhibited are the entire trunk of an indiarubber tree (*Siphonia elastica*), specially obtained from South America, and from which fine Para rubber is obtained. It is a tree inhabiting dense forests on the banks of the Amazon and several of its tributaries, where it is called the "*Seringue*." The chief district from which its caoutchouc is obtained is, according to Wallace, the country between Para and the Xinqui river. The "*Siphonia*" species comprises trees varying from twenty-five to upwards of one hundred feet in height, and all contain a milky juice in more or less abundance, though they do not all yield caoutchouc of good quality, that from some of the species being brittle. The fruit is a rather large capsule, composed of three one-seeded pieces, which split in halves when ripe. The raw seeds are poisonous to man and to quadrupeds, but macaws eat them greedily, and they are an excellent bait for fish; long boiling deprives them of the poisonous principle, and renders them very palatable. The bulk of the caoutchouc exported from Para, whence our chief supply comes, is obtained from *S. brasiliensis*, which is the one common in the forests of the Province of Para: but that brought down the Amazon and Rio Negro is derived from *S. lutea* and *S. brevifolia*. The thin white milk is obtained by making incisions in the trunk, from which it exudes. The trunk exhibited is thus punctured, and a pocket-shaped receptacle of clay has been attached just below the puncture so as to represent the way in which the milk is caught. This clay receptacle is furnished with a lip, so that the milk overflowing may be caught in the earthen vessels used by the native workpeople. This clay receptacle to the tree holds about a tumblerful, and it requires about three hours to fill if the tree be fruitful; this will give an idea of the rate of flow. When the first cutting ceases to yield, the natives make a second one lower down, and so on until they have exhausted the milk in the tree, which is done by making in all four incisions, all at equal distances. They then pour the milk into larger vessels, gather heaps of Urucari or Inaja nuts, which yield a thick oily smoke, and set them on fire. Now they begin the manufacturing process by covering the wooden forms for sheets, long and flat bottles, etc., with clay (so as to be able to detach the rubber easily afterwards), dip the forms into the milk, and hold them over the smoke. As soon as the milk is dry, they dip them a second time, and so on till the rubber is of sufficient thickness: they then take it off the form, and it is ready for exportation. A tree cannot be again made use of for two years, as it requires that time to recover its exhausted strength. A section of a rubber tree is shown, measuring about 18in. in diameter; also a bottle of the white milk brought from Para, and now coagulated. The actual trunk of the tree is so arranged as to appear to form the foreground of a picture in which the scene is completed in a very ingenious manner, as a painting, the foliage of the trees being represented, the natives at work curing the rubber, carrying the milk, etc.; a small sapling (*Ficus elastica*), actually growing, and planted close to the picture referred to, assists still further the imagination of the visitor. Specimens of the Urucari nuts are shown, and also of crude rubber as imported—fine Para, Negro head or Sernamby, Mangabeira, and Ceara. In the other parts of the exhibit are three other pictures pourtraying all the details of the native work—the collecting of the rubber from the trees, smoke-curing, a rubber-collector's settlement, and a river boat. An actual specimen of such a boat, made of rubber, is also to be seen. Specimens of washed Para rubber, pure solid rubber block, and fine cut sheet used for making tobacco pouches, elastic bands, surgical bandages, etc., are shown, along with drugs, chemicals, and pigments used in the manufacture of rubber goods. Very interesting are also the six specimens illustrating the products of the destructive distillation of caoutchouc.

Elastic Rubber Thread.—The manufacture of this is one of the most important branches. This thread is used for weaving with silk or cotton into elastic webs for boots, braids, and other articles of dress. Amongst these threads are some exceedingly fine vulcanised varieties shown by this firm. A considerable variety of articles used for mechanical purposes is shown, and also a convenient form of matting recently introduced, which is finely ribbed. It is used as floorcloth, and presents several advantages in such use; it is styled "Rabdotos." There are also waterproof and air-proof fabrics, and all varieties of garments; mattresses which can be used on board ship, and, by being inflated, will, in case of necessity, serve as rafts. A camp equipment is shown, consisting of bed, air-mattress, folding-bath, and bucket; playing balls, Macintosh tennis balls, and elastic bands.

The works of this firm were first established in 1824 by Mr. Charles Macintosh, who first applied indiarubber to the waterproofing of articles of clothing; whence the term "Macintosh." The processes used to render rubber non-adhesive and insensible to cold, usually termed vulcanisation, are the invention of Mr. Thomas Hancock, one of the members of the firm. The effect of vulcanising is also to make the rubber permanently elastic, as well as insensible to cold or heat, besides resisting largely the dissolving action of oils or fatty matters. Vulcanisation has enabled rubber manufacturers to produce articles applied by engineers in machines driven by steam or otherwise.

With regard to statistics of the rubber trade:—

	Tons.	Value.	Per lb.
Raw rubber imported in 1886	9625	£2,202,716	or 2s. 0½d.
Raw rubber exported in 1886, chiefly to America, Germany, and Russia	5470	£1,281,199	or 2s. 1d.
Raw rubber manufactured in the United Kingdom	1155	£921,217	
A large amount of other materials used, as cotton, woollen, linen and silk fabrics, iron wire, metal mounts and fittings; also drugs and chemicals, probably		£500,000	
		£1,421,217	
Exports from the United Kingdom of British manufactured goods in 1886		£971,052	
Imports into United Kingdom of foreign manufactured goods:—			
1885	1100	£397,730	or 2s. 6d.
1886	1200	£353,729	

EXPORTS OF MANUFACTURED GOODS FROM THE UNITED KINGDOM.

David Moseley & Sons, Chapel Field Works, Ardwick, Manchester (No. 879).—An extensive exhibit of indiarubber for mechanical purposes; washers, sheet, valves, railway buffers, steam packing, ball valves, bearing springs, deckle straps for paper machines, door mats, stair treads, etc. Tubing for chemical purposes, as also delivery and suction hose, and the figure of a diver completely clad in the necessary waterproof garments and helmet, and furnished with hose-gear for supply of air; Anchor linen hose for fire brigades, Simplex cotton belt, vulcanite and ebonite for electrical and chemical purposes; patent Cornscus waterproof garments and waterproof garments of all kinds, especially ladies' cloaks, printed by the new process in most elegant patterns; the new Rex tennis balls, and many varieties of rubber tobacco pouches.

J. **Mandleberg** & Co., Albion Rubber Works, Pendleton, Manchester (No. 880).—Also an extensive exhibit, illustrating the various applications of indiarubber, though paying special attention to waterproof clothing in various styles and materials; ventilated waterproof clothing, Albion and embossed proofing, waterproof pouches.

Besides the foregoing are similar exhibits by Messrs. Broadhurst & Co., Bradford, Manchester; The Salford and Irwell Rubber Company, Limited; William Currie & Co., Caledonia Rubber Works, Edinburgh; Cooper, Box, & Co., 7, Love Lane, Wood Street, London; Bilsland & Co., 99 Princes Street, Edinburgh; and the Ancoats Vale Rubber Company, Limited, Palmerston Street, Ancoats, Manchester.

Isidor Frankenburg, Greengate Rubber and Leather Works, Salford, Manchester (No. 888).—Both indiarubber and leather goods, as well as specimens of crude rubber as received from abroad. It is due to this exhibitor to mention the fact that he has recently patented a new appliance and means whereby the workpeople of the rubber factories may be protected from the very deleterious and poisonous fumes of carbon bisulphide. The arrangement is such that after leaving the tap of the bisulphide cistern the liquid runs along a gutter covered by glass, until it reaches the apparatus where the solution of the rubber is effected, which is surrounded by glass and furnished with slide doors, the whole being covered by a dome connected with the chimney, so as to carry off by the draught all fumes which escape. The work-table and proofing machine are similarly covered over, so that the fumes escaping into the atmosphere of the rooms is reduced to a minimum. Those who know what a terrible malady the carbon bisulphide poisoning induces, and have witnessed the cases, which resemble in some respects those of *delirium tremens*, but differ from this by the peculiar blueness and numbness induced in the hands when dipped in water, will appreciate the boon to the workpeople of any effectual method of avoiding the vapours of the volatile bisulphide. Those interested in the phenomena of bisulphide of carbon poisoning will find the subject exhaustively treated in the excelient article by Dr. Ross in the *Medical Chronicle*, vol. v. No. 2, pp. 257—269.

The Laverine Chemical Co., Abbey Hey, Gorton, Manchester (No. 891).—A very interesting indiarubber substitute, designated "Sea foam," or light white artificial indiarubber, is exhibited by this firm. It is an extremely porous light article, almost resembling sponge in appearance. The writer understands that it is obtained by the action of sulphur chloride upon linseed oil, and also that it possesses physical properties which almost exactly resemble those of indiarubber; and, finally, that it may be mixed with rubber perfectly, and will produce a mass adaptable to all the purposes to which ordinary rubber is applied. Articles of clothing waterproofed with the rubber substance are shown, etc. Amber, or hard, yellow, artificial indiarubber; Nigrum elasticum, or hard black; and Castor, or hard grey artificial rubber; powdered white, yellow and black artificial indiarubber, are also represented by various samples.

GROUP XIII.—BUILDING MATERIAL.

Kneeshaw, Lupton & Co., 41, Oldhall Street, Liverpool (No 892).—Specimens of paving sets from their quarries at Port Nant, N. Wales. A special feature of these sets is the cleavage, and it is claimed for them that they do not become slippery. Specimens of macadam, chippings and breaking stones from the same quarry, are shown; also specimens of limestone, limestone chippings, dust and lumps, as used by limeburners, chemical manufacturers and contractors; also specimens of lime burnt in Hoffman kilns. Analyses of this limestone show it to contain 98 per cent. of calcium carbonate; it is obtained from the Lysfaen quarries of the firm.

Thurstonland Brick & Stone Co., Limited, Brockholes, near Huddersfield (No. 893).—Specimens of bricks and hard York blue stone. The various kinds of brick shown are displayed in a sunk panel of dark red bricks, and a wall of dark red bricks with moulded stone coping. There are shown also special moulded bricks and hard-burnt imperishable engineering bricks. The display of stone consists of specimen steps, palisading stone and platform coping stones, also moulded steps, and coping and cornice stones. This stone, which is known as "hard York blue stone," is said to be very hard and tough, and specially suitable for positions exposed to great wear. The bricks are made from a quality of shale containing 65 per cent. of silica, two cubic yards of the shale producing 1000 bricks. This shale contains a large percentage of iron, which becoming oxidised in the kiln, gives the cherry red colour they possess. Each brick is subjected to a pressure of 14 tons, to make it solid, and the heat of the kiln is such that the bricks are almost vitrified. It is claimed for these bricks that they resist the action of acids, weather and fire, and are not broken by a crushing strain of 390 tons to the cubic foot.

Geo. King Harrison, The Lye Fire-clay and Brick Works, Stourbridge (No. 894).—The exhibits of this firm include gas retorts in one piece and in segments, firebricks, samples of best Stourbridge fireclay, as raised from the mines of the firm, and the same after being subjected to intense heat, after which no contraction is shown. Stourbridge clay used in the manufacture of glass-melting pots, linings of potash furnaces, etc. This clay has been well known for more than three centuries. It is estimated that the trade in firebricks finds employment for about 3000 hands, and that the quantity of clay raised for this manufacture amounts to about 200,000 tons per annum.

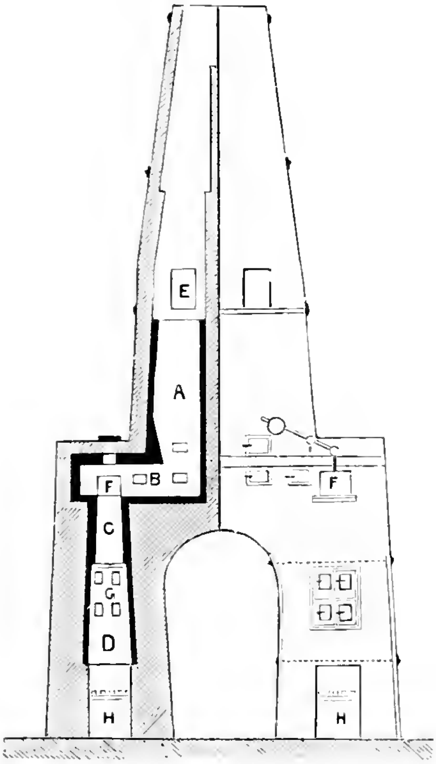
The Croft Granite, Brick & Concrete Co., Croft, near Leicester (No. 895).—Articles for building, paving and decorating in Croft adamant. String courses, panels, medallions, and other ornamental mouldings. Paving slabs, plain and grooved.

Thomas Lawrence & Son, Brackwell, Berkshire (No. 896).—A piece of gauged and carved brickwork in the form of a niche, the bricks used being those made by the firm, and known as No. 8, "Orange Red Rubbers." The erection stands on a base built with red-pressed facing bricks. The special feature claimed for these bricks is that they are solid throughout, and free from air or sand holes; and that though soft enough to be readily worked and carved by hand, they will yet stand exposure to the most severe weather. They are made from clay found on the edge of the Bagshot Sands, on the verge of the London clays.

William Mellor, Gorton Brook Pottery, Ardwick, Manchester (No. 897).—Chemical stoneware pottery, used in condensing, evaporating, collecting, crystallising, or mixing of chemicals, and consists of receivers, taps, pipes, mugs, jugs, funnels, test trials, jars and dishes.

Edward Brooke & Sons, Fieldhouse Fireclay Works, Huddersfield (No. 898).—This firm exhibits white and coloured glazed bricks, sanitary tubes, silica firebricks, white and coloured glazed sinks, salt glazed earthenware cisterns, glass tank boats, glass tank syphons, gas retorts and tuyeres. The silica firebricks are made from ganister, a silicious, fine-grained sandstone in the lower coal measures known geologically as the "Ganister Beds." The analysis of this ganister is 98 per cent. of silica, 1·50 per cent. of alumina, 0·50 per cent. of iron, lime, etc. Special features of this exhibit are the fireclay blocks, used for plate, window-flint and bottle-glass furnaces. Most of the English furnaces are supplied with these blocks. This firm consumes annually about 35,000 tons of raw material, and the value of the articles manufactured amounts to about £60,000.

Otto Trechmann, West Hartlepool (No. 899).—Handsome model of Dietzsch's patent kiln, for the continuous burning of cement, limestone and other materials. Explanatory drawing of the same. Apparatus for testing the tensile strength, soundness, fineness, setting time, etc., of cement. Calcimeter for estimating the amount of carbonate of lime in the slurry. Sundry sample specimens of chalk, clay, slurry, clinker, Portland and other cements. Briquettes and standard sand for testing. Set cement and concretes, illustrating the manufacture, testing and application of cement. In the Dietzsch's kiln it has been sought to combine the principle of the cone kiln with the advantages of the circular kiln, and instead of allowing the heat to circulate through the mass, to pass the material by the aid of gravitation through a canal kept at a constant high temperature. This is achieved by dividing the vertical shaft of the former horizontally into two parts and connecting the upper with the lower by a horizontal channel, thus reproducing in a manner several chambers of the circular kiln; not in a horizontal plane but vertically superimposed. The upper part of the lower shaft is retained at a clinkering temperature by the addition of fuel, and all superincumbent weight on the clinkering cement is obviated, thus permitting it to descend by its own weight so soon as the decrease in volume, due to the completion of the calcining process, takes place. With this movement a disturbance of the mass ensues, and the incipient cooling, together with a slightly conical form of the shaft, tend to prevent adhesion. The annexed figure represents a double kiln, produced by simply building two kilns back to back. The individual kiln consists of three essential parts, of which the two lower ones, C and D, lie in a different vertical plane from the upper one A. A may be called the warming or pre-heating chamber, C the calcining chamber and D, a continuation of it, the cooling chamber. At E are doors or openings for charging A with dried slurry. The covered calcining chamber C is connected with A by means of the arched horizontal channel B, and the cooling chamber D terminates with ordinary firebars H, through which the air to supply the whole system enters. The finished clinker is drawn at H, and the calcining chamber C, as the central point of the system, is the one where the main operation of burning is carried out, where the cement becomes soft and plastic, alters its form and eventually welds into larger or smaller blocks and inclines to adhere to the walls of the furnace. This part is therefore arranged in such a manner that it is accessible from all directions, by means of small openings G, for the removal when necessary of adhering lumps. In order to put the kiln into operation A is filled with dried slurry, D with clinker, and C with alternate layers of dried stuff and coal or coke. After the fuel is fired, the heat escaping from C strikes through the direct slurry lying on B and in A and is almost totally absorbed, only sufficient passing to keep up the requisite draught in the chimney-like continuation of A. As soon as the cement is sufficiently calcined in C a quantity of clinker is drawn at the bars, causing the whole mass in C and D to sink; thereupon fuel is introduced through the furnace doors F, and preheated slurry is, with the aid of flat shovels, turned over from B into C, the fuel and dried mass being placed in layers until C is filled again. This operation is repeated at intervals of half or three-quarters of an hour, and the burning proceeds continuously without further interruption than may be caused by the adhesion of clinker to the sides of the furnace. It is apparent from this description that the fuel is utilised to its utmost extent, for the cold air entering at the firebars, coming into contact with the hot descending clinker, becomes gradually heated to a white heat before reaching the fuel, thus producing a combustion akin in intensity to that of the regenerative furnace. It is, however, not completed at this point, but the mixed products of combustion, which entail such an enormous loss of available heat in the ordinary kilns, here strike the dried mass lying at B, and which at this point is in a state of bright cherry redness and incipient fusion, and are completely burnt. This system of burning cement, lime, etc., therefore offers a double advantage to most previous systems—firstly, in the complete utilisation of the fuel, combined with a minimum loss of heat, since the unavoidable radiation is restricted to one part of the kiln; secondly, because the mass to be burnt remains for the shortest possible time at the point of greatest heat, the critical period where over or under calcination so easily takes place. The amount of fuel required for each of the three principal systems in use for cement burning is approximately, per ton of clinker:



For the open or chamber kiln....	22 to 23% of coke, or $4\frac{1}{2}$ to $6\frac{1}{2}$cwt.
.. .. Hoffman type............	17 to 18·5% .. or $3\frac{1}{4}$cwt.
.. .. Dietzsch	10 to 16% of small coal, or 2 to 3cwt.

Or roughly, $\frac{1}{3}$ to $\frac{1}{2}$ of the weight of a cheaper and cleaner fuel.

The Great Rocks Lime & Stone Co., Dove Holes, near Stockport; works, Peak Forest, Buxton (No. 900).—Sample of best lime. Ordinary raw lump limestone. Crushed limestone for chemical and other purposes.

T. C. Brown-Westhead, Moore & Co., Cauldon Place, Staffordshire Potteries (No. 901).—Specimens of all the materials used in the manufacture of china and various kinds of earthenware. All the stages of manufacture are illustrated in a most instructive manner.

Doulton & Co., 17, Deansgate, Manchester; and Lambeth Pottery, London (No. 902).—Stoneware drain pipes, self-adjusting joint and composite joint drain pipes of Lambeth, Rowley Regis and St. Helens manufacture, Gullie's interceptors, patent channels, Doulton peto fireproof flooring, patent silicon tread, blue facing, paving and coping bricks, red and buff terra cotta, water waste preventers, double-valve syphon waste preventers, drop-by-drop flushing siphons for main and branch drains, flushing tanks, grease interceptors, stop cocks, etc., glazed ware, slow combustion grates and mantels; also radiating open tile stoves for halls, etc.

The Troutbeck Park (Westmoreland) Green Slate Co., Limited, Windermere (No. 905).—Specimens of light and dark sea-green roofing slates. The special advantages claimed for these slates are durability, colour and thin cleavage. It is stated that they are from strata composed of volcanic ash, and are therefore more durable than the Welsh slates quarried from ordinary sedimentary deposits; the colour, a soft sea green, either light or dark, said to withstand all climatic influences, whilst the thin cleavage renders it possible to have a strong roof without corresponding increase in weight. One ton of the best slate is said to cover about 27 superficial square yards. These quarries have been worked about 100 years, and it is estimated that at the present time they turn out from 8000 to 10,000 tons of slates per annum, the value of the total production being about £28,000 to £35,000.

Willesden Paper Works (The Patent Waterproof Paper and Canvas Co., Limited), Willesden Junction, London, N.W. (No. 908).—This firm shows a ventilating shaft of Willesden 4-ply paper, for mining and other purposes; awning, illustrating uses of Willesden canvas; tank made of Willesden 4 ply paper, holding water; Willesden roofing, Willesden paper, Willesden rotproof canvas and rotproof scrim, in rolls ready for use. The peculiarity claimed for this paper is that it is rendered waterproof and weather resisting by the so-called "Willesden" process, and that canvas treated in the same way is made rotproof. The process consists of a treatment with a metallic solution, originally discovered by Dr. Scoffern; it has since been improved by Dr. C. R. Alder Wright and others. It is based on the fact that cellulose is soluble in an ammoniacal copper solution. The pores of the paper become thus stopped up by a dried magma of cellulose and cellulose solution formed by treating the sheets of paper with the said solution.

Casebourne & Co., Limited, West Hartlepool (No. 909).—Portland cement, showing the raw material (chalk and clay) from which it is manufactured; the cement as it is when mixed and ready for burning. The same in the form of clinker when burnt, and also in the powder when ground and sifted ready for use; also Faija's cement-testing machine, and Scheibler's apparatus and Arnold's Patent Cement Test Moulding Machine. Apparatus has now been devised by which cement may be almost immediately tested in such a way that perfect confidence may be felt in regard to its behaviour under any circumstances. The object of testing cement is to determine in a short time its quality and the results which may be expected by ascertaining the fineness to which the cement is ground; by its tensile strength (when gauged and treated in a certain manner) at the expiration of three and seven days from gauging, and by observing the increase in strength between those dates; and lastly, by the soundness of the cement—*i.e.*, the absence of either expansion, contraction or cracking, commonly called blowing. Faija's testing machine is intended to facilitate this operation. The ordinary-sized machine, adapted to test briquettes of one square inch section, will test from 1lb. up to 1000lb.; it stands 14in. high, is 14in. long, 3in. wide and weighs under 30lb. It is of the best workmanship and materials, the knife, edges, and all wearing parts being of phosphor-bronze, and special gearing has been arranged so that the strain may not be put on the briquette at too great a speed. The clips of the machine are made to suit the form of briquette adopted by the Metropolitan Board of Works, but can be made to suit other forms at a small extra cost. The firm also shows Scheibler's apparatus for estimating the proportion of lime used in the process of cement-making, samples for testing, test bars, and samples of different kinds of concrete. This Company's works at West Hartlepool produce about 250 tons of cement per week. Hydraulic cements are those which have the property of solidifying under water. They are produced by burning or calcining calcareous rocks containing 10 or more per cent. of insoluble matter. The hydraulic quality depends chiefly upon the amount of the insoluble matter, and the percentage of silica, alumina, magnesia, or iron which it contains. By the calcining the silicates insoluble before the action of heat are modified. The caustic lime and the modified silicates react upon each other in the presence of water and produce a solid stone-like silicate The water contributes to harden the cement by uniting with the silicate formed and producing therewith hydrate. Portland cement is a mortar which is now largely manufactured from chalk and certain kinds of clay. It possesses the property of solidifying and hardening under water, and is therefore said to be a "hydraulic" cement. The chalk and clay are thoroughly ground together with water and the finely-divided mixture termed "slip," is dried and then carefully burnt in kilns. The clinker thus produced is ground to a powder and sifted and is then ready for use. This cement forms the basis of concrete and the artificial stones so largely used in engineering operations.

GROUP XIV.—SUGAR, GUMS, STARCHES, ETC.

Thomas Critchley, 10, King William Street, Blackburn (No. 910).—A prepared form of starch known as "starch gloss."

Thew & Stiebel, 65, Sackville Street, Manchester (No. 911).—Shellacs of all descriptions, viz.: Button, orange and garnett shellacs, as imported by the exhibitors; also the seedlac and sticklac, from which the shellacs mentioned are obtained. White shellac manufactured from the crude shellac. Various gums used in varnish making.

Tootell & Co., Alexandra Buildings, Ormond Street, Liverpool (No. 912).—Exhibited by their agent, **E. J. Scott**, Blackburn.

I. Materials used for the sizing and finishing of cotton, linen, jute, and other textile fabrics, paper, etc.; also for brewing, confectionery, etc.:—*(a)* In Sizing, substances used for laying the fibre, and for causing the size to adhere; also for stiffening the finished fabrics: Farina: Granulated, ground, and sifted, "prime" or ordinary quality, second and commoner qualities; sago flour: finest quality, fine "Sarawack" (Liverpool classification), fine "Borneo" (Liverpool classification); tapioca flour; Indian corn starch; rice starch; wheat starch; rice flour (various qualities); wheat flour (various qualities); dextrin or British gum (various shades); "Virine" (a new preparation from farina). *(b)* Substances used for giving weight and body to the size: China clay (various qualities); French chalk; sulphate of baryta; Epsom salts; Glauber's salts. *(c)* Substances used for strengthening the yarn, giving weight, and preventing the growth of mildew:—Chloride of magnesium ("prime white," German manufacture); chloride of magnesium (English manufacture); chloride of calcium; chloride of zinc (solid and liquid). *(d)* Substances used for softening the size, and giving "feel" to the cloth: Tallow, various kinds; sizing soap; soft soap; prepared sizing wax; paraffin wax, various kinds; Storey's warp softeners, various; "Emolline." *(e)* Prepared sizes: "Lancashire size"; "muciline"; paper stainers' size.

II. Various products of the potato and sago palm, etc. (other than those mentioned before), used in the arts and for food:—*(a)* Of the potato: Glucose, both solid and liquid; crystallised sugar; potato spirit, raw, fine, and wine spirit; caramel, various kinds, for beer, spirits, etc.; potato barley; pearl farina; potatoes; pulped potatoes showing the precipitated starch; photos of machines used in the manufacture of farina. *(b)* Of the sago palm: Photo of a sago palm; section of trunk of sago palm; piths of sago palm; raw sago from the troughs; sago flour; pearl sago (small, medium, large). *(c)* Tapicca: Tapioca plants; bulbs or roots of plant; tapioca flour; flake tapioca.

A variety of articles manufactured from potatoes, and chief amongst these is farina, in its granulated, ground, and sifted forms. Whatever excellence of quality has been arrived at, is by (1) years of careful cultivation of selected seed, certain varieties of the potato yielding not only larger quantities but better quality of starch than others: (2) gathering and storing the potatoes properly. If the tubers are taken up too soon or stored too long afterwards, the quality of the starch they contain is very greatly deteriorated. (3) The avoidance of all chemicals in the manufacture, the process being entirely mechanical. By these precautions it is possible to produce the strongest possible starch of one regular and uniform quality, points of considerable importance, since it is found that in the farina used for sizing the slightest variation in quality is of great concern to the users as likely to cause injury.

For Light Sizing.—11lb. shirtings, 40 yards long, are being sized with ¾oz. of farina alone.

For Heavy Sizing.—Warps of medium counts are being weighted to the extent of from 150 to 180 per cent. (with China clay and the usual chlorides), and this weight is being successfully carried through the weaving process by the aid of farina already mentioned.

The sago palm and its products are also of interest. As in the manufacture of the farina, the same system of careful selection of the best variety of palm, combined with a select method of manufacture, is being carried out, and although the progress is but slow, owing to the length of time which the sago palm requires to arrive at maturity, yet the improvement in the quality of the sago flour produced is very marked.

The "Lancashire Size" and "Muciline" are for use chiefly in hot and dry climates for the sizing and weighting of cotton fabrics; the paper stainers' size for use with delicate shades of colours.

H. L. Lilley & Co., Albert Works, Queen's Road, Manchester (No. 913).

(*a*) *Starches* for various industries. "Crystal" rice starch and rice starch in powder: Indian corn starch, same varieties: "Crystal" wheat starch: farina and potato starch, granulated and in powder, with various kinds of finishing starch for bleachers, calico printers, finishers, and paper makers.

(*b*) *British Gums* of all kinds for calico printers, paper stainers, etc.

(*c*) *Rice Starch* for domestic purposes. Certain specialities are (*a*) some very fine "crystals" obtained by moulding and stoving the starch in blocks of about 20lb. each. (*b*) Some blocks of starch specially prepared, and showing the process of "crystallisation" of starch.

(*d*) *Corn Flour* for domestic uses.

Henry Tate & Sons, 15, Exchange Buildings, Liverpool (No. 913A).—Specimens of refined sugars.

The Crystals are manufactured at the Liverpool refinery, and are of the best quality, it is said, containing 99·9 per cent. of real sugar.

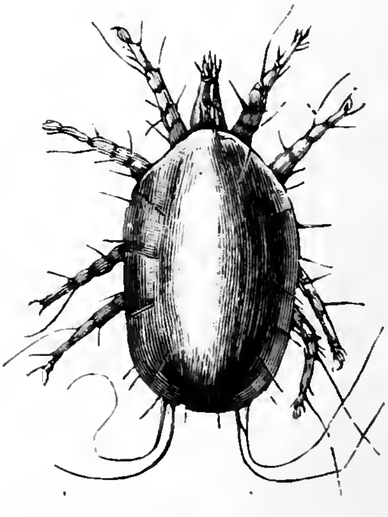
The Cut Loaf Sugar, known as "Tate's Cubes," is made at Silvertown, in London, and is cut ready for use instead of being sold in loaves. It is stated that the mechanical device for producing at once the cube sugar, at the same time maintaining its purity, has enabled this firm to keep an industry in London, which must have otherwise been taken away by its Continental competitors.

The Sankey Sugar Co., Earlestown, Lancashire (No. 914).—In the lower part of this show case are the refined sugars in the bags as sold—the largest 2cwt. each, medium 1cwt., and the smallest size 56lb. each. In the upper part of the case are all the refined sugars made by the firm, and also samples of (*a*) Java raw sugar; (*b*) Peruvian raw sugar: (*c*) Demerara grocery sugar: (*d*) Peruvian concrete sugar (all four made from pure sugar cane, and all containing *acari*); liquor in the various stages of refinery, etc.; (*e*) raw sugar dissolved in water; (*f*) the same liquor after passing through fine cotton filter bags; (*g*) sample of dirt (dried) removed by these filter bags; (*h*) liquor ready for boiling into grain after passing through animal charcoal, the only refining agent; (*i*) sample of the animal charcoal used; (*j*) specimen of black treacle: (*k*) specimen of refined treacle.

The specialities are two very pure varieties, termed "Castor" and "Pulver." Analyses made by the writer and Dr. Burghardt show that these sugars are extremely pure, an average specimen of "castor" containing 99·889 per cent. of real cane sugar, and one of "pulver," 99·922 per cent. Some interesting photographs are shown of sugar cane plantations, raw cane sugar factories: interior and exterior views in the Fiji and Sandwich Islands and West Indies; cane mills, small size for the East Indies and larger size in general use in West Indies: Fryer's concretor, for making concrete sugar: Wetzel's pan used for concentrating raw cane juice: four views of the Sankey Sugar Refinery, and several of places in the West Indies.

Photographic views are shown of the sugar mite (*acarus sacchari*) considerably magnified, and also of a sugar cane in bloom, and a cabbage palm.

The *acarus sacchari* is almost always contained in unrefined sugars, and the average number per pound has been estimated as upwards of 100,000. Filtration through the bag filters removes the creature along with other sedimentary matters. Its food consists chiefly of nitrogenous matter contained in the coarse sugar. The illustration below shows the magnified form of the sugar mite. It is only seen as a very minute moving speck on the surface of a solution of raw sugar. These insects are the cause of the "grocers" itch, from which those workmen who handle the raw sugar suffer.



Stiff & Co., Redcliff Street, Bristol (No. 915).—Specimens of starch and other products obtained from rice.

GROUP XV.—MISCELLANEOUS.

The Wrexham Lager Beer Co., Limited, 14, Brown Street, Manchester; Brewery, Wrexham (No. 916).—This firm exhibits samples of the well-known lager beer so largely consumed on the Continent and in the United States, and which is now enjoying considerable popularity as a beverage, especially in the larger towns of this country. It is produced by the system of bottom-fermentation (Untergährung) followed by the Bavarian brewers, in contradistinction to that of top-fermentation generally adopted in this country. The "mashing process" differs only in detail from that usually followed. It consists essentially in the mixing of malt and water of such a temperature that the ferment of the malt (the diastase) changes the starch of the same into glucose. The clear saccharine liquid or "wort" obtained by the mashing process is then submitted to the sedimentary- or bottom-fermentation alluded to above. This fermentation, which forms the characteristic feature in the brewing of lager beer, is excited by that particular form of yeast which is deposited at the bottom of the fermentation-vats of a previous brewing. This yeast consists essentially of the round-celled variety of the alcoholic ferment known as *saccharomyces cerivisiæ*. The fermentation requires three or four weeks, and takes place in comparatively shallow tuns placed in cool cellars, the temperature not being allowed to exceed 40° F. (4½° C.), which necessitates in summer time a large consumption of ice. During the fermentation the carbonic acid is disengaged in very minute bubbles, and carries up a mere film of froth and yeast, it being chiefly deposited at the bottom. One main object of the lager beer process is to completely remove the gluten and all other oxidisable matters from the "wort." The gluten or yeast is deposited as a viscid sediment during the fermentation, while other matters are oxidised by the oxygen of the air, their destruction in this manner being accelerated by the freedom of the surface of the beer from any protecting layer of yeast and the large area of the fermenting vessels. Lager beer being deficient in alcohol is not suitable for home consumption, since it is impossible to keep it for any length of time in barrels, but it is eminently adapted for export in bottled form. To sum up the chief characteristics of "store" or lager beer, it is less alcoholic, of higher specific gravity, richer in dextrose, albuminoids and carbonic acid than English beers. Further, since ice is used instead of hops to preserve the lager beer the narcotic action of the hop is avoided. Lager beer is eminently adapted as a safe beverage for quenching the thirst in hot weather without inducing that soporific action so characteristic of English beers.

John Johnson & Co., St. Anne's Works, Liverpool (No. 918).—Specimens of various qualities and forms of plumbago or graphite (a native form of carbon, also termed "blacklead") from different parts of the world and in the different stages of manufacture. The price of this article of commerce varies from £9 to over £5000 per ton. An exceedingly fine quality of plumbago but limited in amount is regularly imported from the celebrated mines of Prince Schwarzenberg. None of the native products are entirely suitable for making a really good polishing blacklead. Some descriptions are too hard and gritty, others too soft and dusty, some too pale and with so little body that they will not adhere to the surface of a smooth piece of ironwork. The so-called "prepared blacklead" used for machinery is obtained by separating the lighter portion of the blacklead by grinding, the product of which is dried, ground to an impalpable powder and sieved. The residue—*i.e.*, the heavier portion—is used for making the block blackleads. The grinding of the "natural" and also of the levigated leads is accomplished by means of vertical grinding stones of about one ton weight each, revolving at a certain rate upon horizontal stones of similar proportions. The ground lead passes into machine sieves, which separate the finely ground from the rougher portions; the latter falling again into the millstones, is re-ground, whilst the finished powder is conveyed by means of elevators into the mixing-room, where the different qualities are mixed together—various proportions for the preparation of block black-leads and powder leads. The blocks of blacklead are formed and polished by special machinery.

This firm also exhibits various forms of laundry blues manufactured from the ultramarine of commerce, and indigo blues for laundry purposes are also exhibited. The ultramarine blue is exhibited in the various stages from the raw materials to the finished article. [See also Nos. 753 and 754.]

Bryant & May, Limited, Fairfield Works, Bow, London, E. (No. 919).—A complete selection of household matches, also wax vestas and wax tapers for gas lighting. Specially to be noticed are the specimens of patent safety matches. The principle observed in making the latter is best exemplified by a brief description of the modes of preparation of ordinary and safety matches. In the former the wood splints are tipped with a composition containing amorphous phosphorus mixed with oxidising agents, which cause the phosphorus readily to inflame on friction. Such oxidising agents are, *e.g.*, saltpetre, chlorate of potash and red lead. Other accessories are glue and finely powdered glass. Now, in the latter (the safety matches), the splints are simply tipped with a composition containing the oxidising agent only, the rubber on the box being painted with a solution of glue containing amorphous phosphorus and powdered glass. The matches are thus rendered at once non-poisonous and incapable of ignition under ordinary circumstances.

Jewsbury & Brown, 113, Market Street, and 44, Downing Street, Manchester (No. 919a).—Aërated waters and beverages generally known in the trade as mineral waters—Soda water, seltzer water, potash water, lithia water, carrara water, magnesia water, Vichy water, simple aërated water, lemonade, ginger ale, quinine tonic water, ginger beer, horehound beer, champagne cider, Brin's oxygen water, in bottles, half-bottles, and siphons, for which accuracy of preparation and perfect purity are claimed. One speciality in siphons is the metal part, which is of pure English block tin, thus absolutely avoiding any injurious metallic impregnation. Specimens of the pure English tin pipe are shown. The materials used by this firm in the manufacture of artificial mineral waters and aërated beverages are represented. According to analysis the soda water contained 5 grains of bicarbonate of soda; the potash water, 20 grains of bicarbonate of potash, and the lithia water, with potash, 5 grains of carbonate of lithia, and 15 grains of bicarbonate of potash per bottle, or half imperial pint; the seltzer water was found to contain the more important mineral constituents of the natural spring.

Frederick King & Co., Limited, 26, Waring Street, Belfast, and 6, Bishopsgate Avenue, London (No. 920).—The following is a list of the exhibits of this firm:—Edwards's preserved potato—a granulated preparation of the fresh potato. Edwards's desiccated soup—a dry preparation of vegetables and extract of beef, and his white (vegetable) soup. The potato was first preserved by a former member of the firm, the late Mr. Downes Edwards, in 1840 (see Dr. Ure's "Dictionary of Arts," etc.). It was quickly adopted by H.M. Navy, and for sea dietary generally. The effect of being able to carry this anti-scorbutic vegetable at sea materially assisted in expelling the scurvy, which formerly was very destructive to life on board ship. Edwards's patent desiccated soup is a mixture of beef with the potato and other vegetables, the principle of preservation being the same as in the preserved potato—viz., the entire removal of the water, which enables both the animal and vegetable substances to keep for any time and in any climate. The white desiccated soup is a preparation of vegetables only, adapted for use with milk. The annual production varies considerably, the requirements of H.M. Government increasing largely when any war arises abroad, as recently in Burmah and Afghanistan. In quiet times 3000 to 4000 tons of potatoes and other vegetables are manufactured by this firm, and from 300 to 400 tons of beef represent the animal raw material required for the desiccated soup manufacture. The force value of 1lb. (dry) of Edwards's desiccated soup is said to be about 500 foot tons, and the animal and vegetable elements are so proportioned as to produce a diet in which the nitrogen, carbo-hydrates and mineral substances exist in suitable proportion. The concentration is effected in localities where beef and vegetables are very low in price, and its transport in the concentrated form being trifling, a very cheap and nutritive food is thus obtained.

Bratby & Hinchcliffe, Sandford Street, Ancoats, Manchester, and 146, Minories, London, E.C. (No. 921).—Various essential oils, fruit essences, syrups and cordials, citro-chloric acid, salts for natural mineral waters, lime juice, harmless colours, and sundries connected with the aërated water and confectionery trades. The pure soluble de-resinised fruit essences, essential oils, etc., are used in the manufacture of aërated beverages, and for confectionery purposes. The special feature of these articles is their solubility (mixing perfectly bright and clear with water or syrup) while they impart rich, fruity, aromatic flavours to the drinks. This firm also shows specimens of the various chemicals used in the trade. Salts for mineral waters, prepared by a compounding which is based on analysis of the natural mineral springs, such as Seltzer, Vichy, etc. Citrochloric acid is used as a substitute for citric and tartaric acids. It is a mixture containing 75 per cent. of the acid of lemon juice, and 25 per cent. of hydrochloric acid. One fluid ounce is equal in strength to one ounce of citric or tartaric acid crystals, while the cost is about one half. The approximate annual production of these articles represents a value of about £100,000.

Morgan, Lomas & Co., Crumpsall Vale Match Works, Blackley, near Manchester (No. 926).—Ordinary household matches of various brands, household dry soap, and Hoffman's rice starch. A detailed account of the manufacture of these matches appeared in the *British Journal of Commerce* for February, 1887. The illuminating power of each match is 0·75 candle light. The total value of the English match manufacture is estimated to be about 1½ to 2 millions sterling, one half of which amount is spent in raw materials.

Burroughs, Wellcome & Co., Snow Hill Buildings, 67, Holborn Viaduct, London, E.C. (No. 928).—The following specimens are exhibited by this firm :—Kepler extract of malt, Kepler solution of cod liver oil in extract of malt, hazeline (a distillate of witch-hazel), beef and iron wine, tablets and tabloids of compressed drugs, strophanthus (African arrow poison, a heart tonic), digestive ferments (zymine, pepsin, etc.), pure terebene, medicine chests and cases fitted with compressed drugs, etc.

Jacob Barstow, Filter Works, Pontefract, Yorkshire (No. 931).—Filters of various patterns, such as domestic filters, tank filters, table filters, emigrants' filters, tourists' and pocket filters. The oldest style of water-filter is the old drip stone, used very many years ago. They were huge stones hollowed out into the shape of a basin and fixed in a frame, and a vessel placed underneath to catch the water as it filtered or dripped through the stone. About thirty years ago they were made of a more compact form, a slab of stone being cemented across the middle of an earthenware jar, a space underneath being left for the filtered water. Two taps were provided, one to draw off the filtered water, the other to draw off the dirty water. This style of filter was used until it was recognised that "stone" was a mechanical filter, and had no effect on the matters in solution, when it was superseded by such modern filters as are shown by this firm. In these filters the water has first to pass through "natural stone," which removes all suspended and mechanical impurities, and then through a layer of "specially prepared carbon." The carbon being thus kept clean and free from suspended impurities can exercise its full purifying power on matters held in solution in the water, so that the water is first filtered and afterwards purified. The filters are so constructed as to be readily taken to pieces for the purpose of cleansing and examination. The water is said to be cooled and aërated in passing through the apparatus.

Slack & Brownlow, Canning Works, Upper Medlock Street, Manchester (No. 932).—The exhibits of this firm comprise filters for household, military, and manufacturing purposes, the largest of which is capable of purifying 500,000 gallons of water per day. The filtering medium in these filters is compressed carbon.

James & Joseph Clayton, 139, Higher Cambridge Street, Manchester (No. 937).—Natural stone filters with or without charcoal, for domestic purposes, immersion in cisterns, etc., also pocket filters on the same principle, for tourists, etc. The filtering arrangement consists of a hollow cylinder of natural stone cut out with machinery ; this cylinder is filled with charcoal, and there is also a layer underneath, so that the stone filters the water, and the charcoal purifies it after it has passed through the stone. In this arrangement it is sought to imitate the filtration which takes place in nature through beds of rock. The stone cylinders employed are cut out of solid blocks of porous sandstone, in such a manner that the core taken from a large cylinder can be used for making a smaller cylinder. By this method a block of stone 2 feet square can be made to yield no less than ten cylinders, varying in size from the core 1½ inches in diameter to the outer cylinder 2 feet in diameter. Before the application of machinery the entire core of these cylinders was chipped out with a chisel.

Liebig's Extract of Meat Co., Limited, 9, Fenchurch Avenue, London, E.C. (No. 938).—The well-known extract of beef, ox tongues, corned beef, meat meal, etc. These products are manufactured principally in South America or other grazing countries where large herds of cattle are at hand. The extract of meat is prepared from the flesh of cattle not less than four years old so as to ensure it being healthy and mature. In the season this firm slaughters over 1000 oxen per day, and since 1865, when the company was established, the number of cattle slaughtered amounts to 2,600,000 head, representing a value of £8,000,000.

Evans, Sons & Co., 56, Hanover Street, Liverpool (No. 939).—This firm exhibits raw Montserrat lime fruit juice, as received in its filtered state, also the cordials, sauce, bitters, tablets and jujubes made therefrom. Specimens of the fresh fruit itself are also shown.

The lime tree (*Citrus limetta*) is a member of the orange family, and grows well in all the West India Islands. It requires a light, loamy and somewhat stony soil, and an elevation, depending upon latitude, from sea level up to 500ft. The trees are planted 15ft. apart, and come into bearing in about six or seven years, but light crops are often gathered from trees at five years. To ensure large and permanent crops, the trees require to be regularly pruned and kept free from all parasitic growths, such as Loranthus, etc. They are also greatly benefited by tillage, loosening of the soil around the roots, and being kept free from grass and weeds.

The annual mean temperature of Montserrat at sea level is given at 78° F., and the annual rainfall at 59in. These conditions are evidently those most suitable for the successful cultivation of lime trees.

The lime fruit harvest is heaviest from September to January, but a good supply of fruit is yielded throughout the whole year. The fruit, after collection, is taken to central factories, where it is sliced by machinery, and then squeezed in huge wooden presses, the juice being run into puncheons and quickly bunged up. This is a most important point in preparing the juice in a tropical climate, for if exposed it would rapidly decompose. The choicest fruit alone is used, and only about two-thirds of the juice is pressed out, thus ensuring greater freedom from mucilaginous and pulpy matter. The further pressings, together with the juice of unsound fruit, is evaporated to the consistence of treacle, and sent over to this country for the manufacture of citric acid. The export of lime juice, both crude and concentrated, is now nearly 100,000 gallons per annum.

The Distillers Co., Limited, 12, Torphichen Street, Edinburgh (No. 940).—A collection of grain and malt whiskies, London gin, and other spirits. Spirits and whiskies for export in bottle. The Distillers Company was formed by the union of the seven largest distillers in Scotland, and they subsequently acquired the Phœnix Park Distillery in Dublin, and the Tooley Street Distillery in London. The actual output of spirit is 10,000,000 gallons a year, the plant being capable of producing 13,000,000 gallons if at full work. The capital is £887,600, and there is in addition a debenture capital of £450,000. The exhibit (in the two front compartments) consists of different kinds of spirits and whiskies, chiefly grain whisky, some of which is very old. Also gin, spirits of wine, and British brandy from the Tooley Street Distillery. The Company also exhibits Squire's patent yeast, of which they are the sole manufacturers. About 300 tons of foreign yeast are imported every week into England, of an annual value of £840,000. It was believed that pressed yeast could not be made in Great Britain owing to the excise regulations. Dr. Squire, however, succeeded in devising a process which was approved by excise, and the manufacture commenced on a large scale only 18 months ago. The production already amounts to 2000 tons a year, and when the process is at work at all the distilleries of the Company the production will be about 120 tons weekly, or say 6000 tons a year. At present the yeast is made only at Cameron Bridge and Port Dundas Distilleries.

Archibald Lauder, 76, Sauchiehall Street, Glasgow (No. 941).—The exhibitor shows samples of materials used in the manufacture of pure malt whisky, illustrating the various stages in the process of distillation; also a working model of a "Multiple Pot Still," and samples of whisky. The following is a synopsis of the method pursued in the distillation of pure malt whisky. Samples of the different stages herein enumerated are exhibited along with whisky, old and matured:—

No. 1. The barley received from the farmer is stored in large barns or lofts. From the loft the barley is shot down into a cistern, where it is immersed in water, and allowed to remain for some 40 to 60 hours, till it is thoroughly swelled and germination has just commenced.

No. 2. Out of this cistern it is run through a shoot into the "couch" where it lies a day or two; it is then removed to a cool barn with a composite floor, where it remains some 10 to 16 days, being turned over till it has been thoroughly malted.

No. 3. This stage attained, it is transferred to the kiln, where the vegetation is destroyed by great fires placed under the perforated tile or wire-cloth flooring. After two or three days on the kiln it is dry, and is then called malt.

No. 4. It is then removed to the mill and ground, and when ground is placed in the mash tun, where hot water is run in upon it to extract saccharine matter.

No. 5. After remaining some time, the liquid called "worts" is removed from the mash tun to the refrigerator, the object being to cool the liquor as fast as possible to a certain temperature so as to prevent it being soured, or, as it is technically termed, "blinked."

No. 6. From the refrigerator the "wort" is run into the "wash backs" and yeast is added to cause fermentation. Fermentation is allowed to proceed until the whole of the saccharine matter in the liquid is changed into alcohol. The liquid now is technically called "wash."

No. 7. The "wash" is then removed to the "wash charger" and thence to the "wash still," a large copper boiler with a closed head, to which is attached a copper pipe leading to the "condenser," which consists of a "worm" of copper tubing immersed in cold water. On heating the still the vapours pass and are condensed in the condenser, whence they issue in the form of a liquid technically known as "low wines."

No. 8. After the "low wines" are collected they are removed to the "low wines" and "feints charger," and thence to the "low wines still," a vessel similar to the "wash still," for redistillation.

No. 9. When the vapour arising from the boiling of the "low wines" is condensed, the first product—a strong spirit containing a large quantity of the essential oil of the grain called "foreshot"—is run into the "feints receiver." On testing and finding the liquid free from oil, it is run into the "spirit receiver" until it is found on trial that the liquid is becoming weaker, when the remainder is run into the "feints receiver" and mixed with the "foreshot."

No. 10. That liquid which has been run into the "spirit receiver" is the pure whisky, which is pumped thence to the spirit store and vatted. The produce of each week's distillation, or "period," as it is called, is kept separately.

The origin of distillation seems to be lost in antiquity. Although the Greeks knew the art of evaporating water and extracting the aromatic principles of plants, they had but crude ideas as to the art of distillation. The Romans knew nothing about brandy. Pliny, who wrote during the first century and to whom we are indebted for a treatise on wine, nowhere alludes to it.

It is said that the first navigators of the islands of the Archipelago obtained fresh water by boiling sea water and receiving the steam in the sponges placed over the vessels for that purpose.

It is probable that the art of distillation originated with the Arabs, who, from the earliest times were acquainted with the extraction of scents, and who introduced their processes successively into Italy, Spain, and the south of France. The word "alembic" is composed of two Arabic words and is found in writings previous to the 10th century. Raimond Sulle, an alchemist of the 13th century, mentions eau-de-vie and alcohol, and describes the method of obtaining eau-de-vie by means of fixed alkali, a process for which Basil Valentine substituted lime in the following century.

J. Rubée describes a process which he found in the writings of the ancients, consisting of the reception of vapour in very long winding tubes immersed in cold water. Towards the end of the 17th century, B. Porta, a Neapolitan chemist, published a treatise on distillation, and it is evident that the apparatus described by him served as a model for succeeding inventors.

N. Lefebore published in 1651 the description of an apparatus by which he obtained pure alcohol by one distillation, and he was followed by numerous inventors, but distilling apparatus up to the close of the 18th century was only very slightly modified, the variation consisting chiefly in increased size.

The inventions of Mr. Edward Adam in 1800 and of Mr. Isaac Bérard in 1805 marked an epoch in the history of distillation, and these have been succeeded by a host of others culminating in the "Multiple Pot Still," a model of which is exhibited. The special feature of this still is that it is capable of making whisky of a fine "aged" character direct from the "wash" and "low wines," purifying it from the fusel oil which is such an offensive and dangerous ingredient in much of the whisky regularly consumed. There are two kinds of stills in use in this country—*i.e.*, the old pot still and the Coffey patent still. The first is that used by the whisky distillers, and with it three separate distillations have to be made before what is called "finished spirit" is obtained. Even then only about one-fourth part of the third distillation is really finished, the remainder requiring to be distilled over and over again. The Coffey still is that used for making "silent spirit" for the gin rectifiers, and is employed by all the large London distillers. It finishes the spirit in one operation, but it may be pointed out that its "silencing" the whisky flavour is only apparent, and this enables "silent spirit" to be made from every kind of fermentable material, including that produced by the chemical action of sulphuric acid on potato, beetroot, inferior or damaged cereals, or even on sound grain, which saves the cost of the necessary malt in brewing, and allows to creep into consumption a most deleterious form of alcohol infinitely more poisonous than the coarsest make of genuine whisky or brandy.

The general principle embodied in this invention may be thus briefly stated: The hot alcoholic vapour is made to impinge upon numerous inverted copper dishes arranged throughout the column of the still. Upon these the vapour partially condenses, depositing the heavier poisonous impurities in conjunction with the excess of water, which drip into separate side receptacles from which they are conducted by dropping pipes to the lowest compartment of the still, whence they are discharged in one continuous independent stream while the purified alcohol, with its œnanthic or flavouring ether, passes over as a finished spirit. "Feints" and "low wines" are unknown in this process, and only a very small modicum of weak spirit is required to be held over at the end of each distilling period. Even this, however, can be dispensed with, and the most remarkable feature of the operation to a practical distiller is the fact that the "foreshot" is equal to matured pot-still whisky.

The quantity of spirits consumed as beverage in the United Kingdom is as follows:—

Year 1884—85..	England	16,322,991	gallons.
	Scotland	6,629,361	,,
	Ireland	5,069,028	,,
	Total......	28,021,380	,,
Year 1885—86..	England	15,290,816	gallons.
	Scotland	6,297,265	,,
	Ireland	4,751,670	,,
	Total......	26,312,851	,,

The quantity of spirit distilled in the United Kingdom was:—1884—85, 41,006,486 gallons; 1885—86, 38,961,842 gallons.

The number of distilleries at work, was, in each country:—England, 10; Scotland, 127; Ireland, 27; total, 164.

It is estimated that the following amounts of raw material were used:—Malt, 928,919qrs.; unmalted grain, 986,366qrs.; molasses, 341,087cwt.; rice, 167,513cwt.

The quantity of British spirits remaining in bonded stores at the close of the year was—1884, 59,245,624 gallons; 1885, 64,405,817 gallons.

The amount exported being—1884—85, 2,588,078 gallons; 1885—86, 2,808,198 gallons.

The following table shows the consumption of British and foreign spirits in the United Kingdom during the twenty years ending 1885:—

Year.	Gallons.	Per Head of Population.
1866	29,769,000	0·99
1867	29,090,000	0·96
1868	28,610,000	0·94
1869	29,624,000	0·96
1870	31,707,000	1·02
1871	34,454,000	1·09
1872	33,618,000	1·06
1873	37,779,000	1·19
1874	40,510,000	1·26
1875	42,427,000	1·31
1876	41,796,000	1·28
1877	40,420,000	1·22
1878	40,722,000	1·23
1879	38,475,000	1·15
1880	35,761,000	1·05
1881	37,094,000	1·05
1882	36,916,000	1·03
1883	36,765,000	1·02
1884	36,634,000	1·01
1885	35,956,000	0·99

LIEBIG'S WINE CO., 12, St. Helen's Place, London, and 68, Highfield Street, Liverpool (No. 942).—Liebig's Beef Wine with quinine, pepsine or iron; Liebig's invalid and tonic port wines; extracts of malt and meat; also malt and meat wine, and health sweets. All these preparations are intended for invalids, the object being to condense the largest amount of nourishment in the smallest and most palatable form. This firm produces over 38,000 dozen of the beef wines annually, and consumes, in preparing these and extract of beef, 12,000 head of cattle, 287 tons of barley, and 256 pipes of wine.

THE LONDON AND COUNTIES TEA CO., Moulton Street, Strangeways, Manchester (No. 943).—Model of a Chinese junk, laden with original packages of various growths of tea from the tea districts of China, India, and Ceylon, including fine Darjeeling pekoe; Assam pekoe souchong; Ceylon pekoe; Moning, Kaisow, Kintuck, and Ningchow congous; Formosa Oolong; Moyune, young hyson, and gunpowder; Lapseng souchong; Foochow and Canton scented orange pekoe; and scented caper tea. Tea was first imported into Europe by the Dutch East India Company, in the early part of the seventeenth century; but it was not until the year 1666 that a small quantity was brought over from Holland to this country by the Lords Arlington and Ossory, and yet, for three generations past, tea has been reckoned among the principal necessaries of life by all classes of the community. To provide a sufficient supply of the beverage produced from this plant, many thousand tons of the finest mercantile navy in the world are annually employed. The plant is indigenous both to China and Japan, and has been used in the former country from the earliest times: but it is only a particular part of the central provinces which is distinguished as the tea country of China. The plant is a shrub, having the botanical name of *Thea*, and its leaves constitute the tea of commerce. The first crop of leaves is not collected until the plant is three years old, after which they are gathered three or more times a year, generally in April, June, and August, the earliest gathered leaves having the most delicate and aromatic flavour. In 1834, a committee was appointed to consider the question of introducing tea cultivation into British India, and a scientific party was sent to explore the newly-acquired province of Assam, a district in the north-eastern extremity of India, and to make special inquiries respecting the tea-growing there practised. The result was that a Mr. Bruce was selected to superintend the formation of Government nurseries: and, with the aid of Chinese seeds, Chinese plants, and Chinese cultivators, he proved beyond doubt the possibility of producing good tea in India. This profitable industry is now well established in several of the provinces of our Indian Empire. Mr. Goschen, the Chancellor of the Exchequer, in his annual financial statement this year, stated that "the consumption of tea had doubled between 1857 and 1887. In 1857 the consumption was 2·45lb. per head of the population, whilst in 1887 it was 4·87lb. per head. Ten years ago, 156,000,000lb. of tea were imported into this country from China, and only 28,000,000lb. from India; in 1886, England imported 145,000,000lb. from China, and 81,000,000lb. from India, thus showing that the importation of tea from India had increased threefold." The customs duty on tea is now 6d. per lb., and the total weight of tea on which duty was paid in 1886 was 178,893,880lb., producing a revenue of £4,472,347 to the National Exchequer.

JOHN L. JOHNSTON, 10, Trinity Square, Tower Hill, London (No. 947).—Johnston's fluid beef, or bovril, bovril lozenges, bovril lozenges peptonised, bovril cream lozenges, bovril and iron lozenges, peptonised fluid beef, beef and iron wine, beef flour, beef flour peptonised, and beef flour soup. The special feature claimed for these preparations is the addition of albumen and fibrin, the nutritive constituents of meat, to the extractive or stimulating portion. The manufacture is carried on in Canada and America. The juices of the meat are evaporated to a thick syrup in steam pans, and this syrup is mixed with the powdered meat and other substances. From 30 to 48 tons of beef are required daily by this firm for their manufactures.

HENRI NESTLÉ, 9, Snow Hill, London, E.C. (No. 948).—Samples of the well-known condensed milk, Swiss milk, and milk food. The latter is composed of milk, wheaten bread, and sugar.

PEARSON & Co., LIMITED, Cambridge Street, Lower Broughton, Manchester, and Dunster House, Mincing Lane, London (No. 951).—Raw chicory and specimens of chicory in the different stages of manufacture; also the various forms of packages in use for the home and export trades. French coffee and dandelion coffee are also shown, and the various packages in which they are sold. Chicory has been in use in England for nearly 40 years, but has only been scientifically manufactured within the last 15 years. The trade in this article has been considerably retarded by the excise regulations. The approximate annual production of manufactured chicory in the United Kingdom is 100,000cwt., valued at about £175,000. This includes both the English grown, which is only a small item, and the foreign imported. At least 90 per cent. of this is consumed in the United Kingdom.

BENJAMIN ROBINSON, Church Street, Pendleton, Manchester (No. 953).—Natural sparkling wines made from English fruit: universal champagne, sparkling cowslip wine, sparkling raspberry wine, British or home-made wines, fruit cordials, and soluble essences of lemon, orange, and ginger. These wines are produced by the fermentation of the juices of English fruits and foreign white grapes, or from refined cane sugar, flavoured with fresh flowers or fruit. The process is exactly similar to that used on the Continent for the production of sparkling wines from grapes. Some of these wines are stored four years before they are fully matured. The "British wines" are free from added alcohol, and are made solely from fruit and sugar. Not being liable to excise duty, there are no available returns as to the annual production and consumption. "Fruit cordials" are made from the juices of various fruits. The fruits are subjected to hydraulic pressure, and the juice, after being clarified, is mixed with sufficient refined cane sugar to preserve it. They are free from alcohol, and are frequently called "non-alcoholic wines."

The meetings of the London Section will be held on the first Monday in each month.

Communications to be addressed to the Local Secretary.

THE WELDON-PECHINEY PROCESS FOR THE MANUFACTURE OF CHLORINE FROM CHLORIDE OF MAGNESIUM.

BY PROFESSOR JAMES DEWAR, M.A., F.R.S.

It will be in the memory of my hearers that the late Mr. Walter Weldon, just before the sad event which deprived industrial chemistry of his services, had been actively engaged in attempting to develop a second chlorine process. It is a fact—and a fact of which I have no doubt Mr. Weldon was fully conscious—that it is a most rare thing for one man to make two great sucesses as a patentee dealing with the same subject. Yet he was always hopeful of the success of this new process, which was patented on the 23rd June, 1884, under the title of "Improvements in obtaining, partly in the free state and partly as vapour of hydrochloric acid, the chlorine of the chloride of magnesium, of aqueous solutions of chloride of magnesium, or of mixed solutions of chloride of magnesium and chloride of sodium." It would take too much time and space to go into the history of previous attempts to economise chloride of magnesium. Suffice it to say that though numbers of patents have been taken (including several by Mr. Weldon himself at about the time of the industrial application of his great process for the regeneration of manganese) for the direct utilisation of magnesium chloride in the production of chlorine, none have been successful. Before proceeding to a description of the process I should say that, besides the patent already mentioned, there are others, taken at the same time and subsequently, partly based on suggestions of Mr. Weldon's, but chiefly the inventions of M. Pechiney—namely, patents for the various pieces of apparatus, diagrams of which are shown. I think my hearers will agree with me that the chemical side of this question has not been so difficult to deal with as the mechanical side, and that the development of the process has required the application of engineering talent of the very highest order. In fact the credit for the realisation of this process must be divided between three names—those of Mr. Weldon, M. Pechiney, and the able chief of Pechiney's staff, M. Boulouvard. Mr. Weldon himself pointed this out in the letter which accompanied his account of the process for this Society's report on the Chemical Exhibits at the Inventions Exhibition (see note, p. 526, September, 1885). The process has been worked at Salindres for about five months, on an experimental plant designed for the production of one ton of chlorine per day, and may be briefly described as follows, the description being in great measure in M. Pechiney's own words:—The raw material employed is hydrochloric acid. The process consists of the following operations:—

(1) Dissolving magnesia in HCl.
(2) Preparation of oxychloride of magnesium.
(3) Crushing, breaking, and sifting the oxychloride.
(4) Drying the oxychloride.
(5) Decomposing the oxychloride.

First Operation.—Dissolving the Magnesia in HCl.

The magnesia to be dissolved in HCl is a portion of that which results from the fifth operation. The HCl itself also results in part from the fifth operation, and the remainder from the decomposition of salt. The operation in question is somewhat difficult, owing to the considerable rise in the temperature which it produces. It has to be performed slowly to prevent the solution from boiling, which is apt to occur with violence. To this end the operation is performed in an ordinary well, similar to those used in the Weldon manganese process. The agitator is put in motion; the hydrochloric acid is run in slowly, and magnesia is then added little by little as fast as it will dissolve. When the temperature of the solution reaches the point of ebullition the operation is stopped for a short time, to allow the solution to cool. [One means of moderating the elevation of the temperature consists in employing, for the saturation of the acid, not magnesia only, but a certain quantity of oxychloride *in powder*, resulting from the sifting which forms part of the third operation. This portion of the oxychloride cannot be treated in the decomposing furnace, because it would render the charge too compact, and therefore difficult to be traversed by gases. On the other hand, it will be well understood that the solution in HCl of magnesia, combined with $MgCl_2$, will disengage less heat than the solution of magnesia alone, the destruction of the oxychloride itself absorbing a considerable amount of heat.]

When the well contains a sufficient quantity of the solution, the operation is terminated by adding to the liquid (which always retains a little acid) some further small quantities of magnesia, in order to precipitate part at least of the foreign oxides (oxides of iron, alumina, etc.), and thus prevent the accumulation of these impurities. There is also added a certain quantity of solution of $CaCl_2$ for the purpose of transforming into $MgCl_2$ and SO_4Ca a part at least of the magnesium sulphate resulting from the presence of sulphuric acid in the hydrochloric acid employed. The solution is then pumped into standing vessels, wherein the insoluble matters (oxides and calcium sulphate) are deposited, and the clarified liquor is then ready for the following operation.

Second Operation.—Preparation of the Oxychloride of Magnesium.

The solution resulting from the first operation is evaporated in boilers down to the point at which it will contain not more than about 6 equivalents of water, and is now ready for conversion into oxychloride.

The apparatus in which this conversion of the chloride into oxychloride is performed is illustrated by Figs. 1 and 2 of the accompanying diagrams, Fig. 1 being a vertical section, and Fig. 2 a horizonal section. It consists of an annular sheet iron vessel A resting on rollers *a*, *a*. The bevelled wheel *b* acting on the pinion *c* gives a continuous but slow rotary motion to the vessel A. M is a fixed frame upon which are mounted three agitators G, D, E, as well as the shafts *d* and *f*. These agitators are rotated from the shaft *f* by means of a bevelled wheel gearing with a bevelled wheel on the shaft of the central agitator D, which also carries a spur wheel gearing with two equal spur wheels on the shafts G and E. The fast and loose pulleys B and B^1, driven by a band, give motion to the whole machine.

The quantity of MgO used at Salindres in this operation is about $1\frac{1}{3}$ equivalents per equivalent of $MgCl_2$.

This magnesia is brought to the above described annular vessel by means of a chain of buckets which elevates the magnesia and then lets it descend through a strainer under which the horizontal rotary motion of the annular vessel brings successively every portion of the $MgCl_2$ which the latter contains. The operation lasts only about twenty minutes. The whole mass becomes very hard and during solidification disengages much heat. It is then in the form of solid pieces, of different sizes. This operation finished, the material is discharged from the annular vessel into little waggons, which, by means of a lift, bring it to an upper floor, where the reaction, which was not quite finished, continues for some time.

The composition of the oxychloride in this state is approximately as follows:—

Impurities..	4·00	
Water	41·16	
$MgCl_2$	35·00	Cl=26·16 per cent.
MgO	19·84	=1·316 equivalents per equivalent of $MgCl_2$.
	100·00	

Third Operation.—Breaking, Crushing and Sifting of the Oxychloride of Magnesium.

The oxychloride produced by the preceding operation is in the form of pieces of various sizes along with a small quantity of powder. It is necessary to reduce this material to morsels, of which the largest shall not be larger than a walnut, and further to clear these pieces of all dust, which might, when in the decomposing furnace, prevent the free passage of air through the mass.

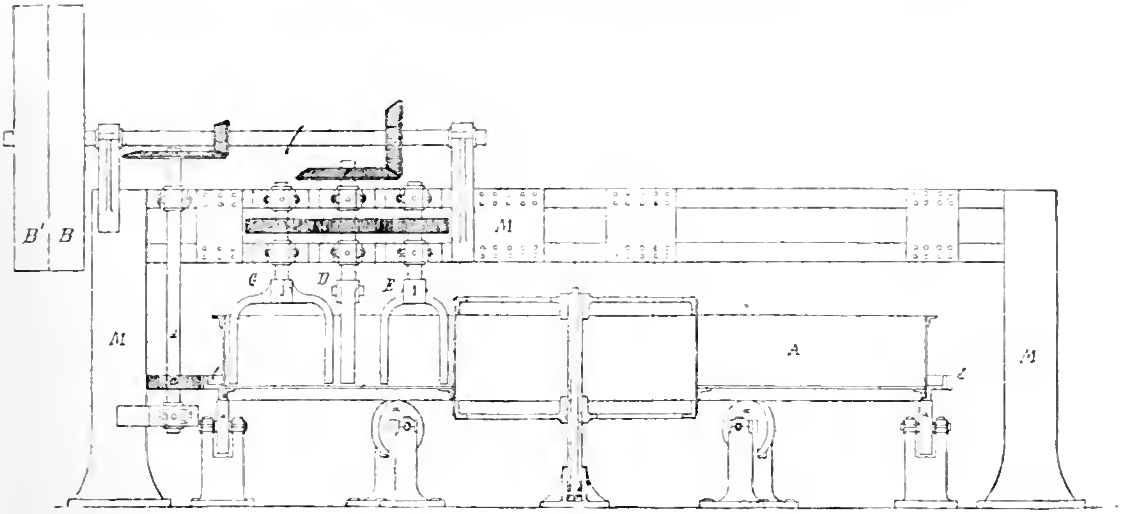

FIG. 1.

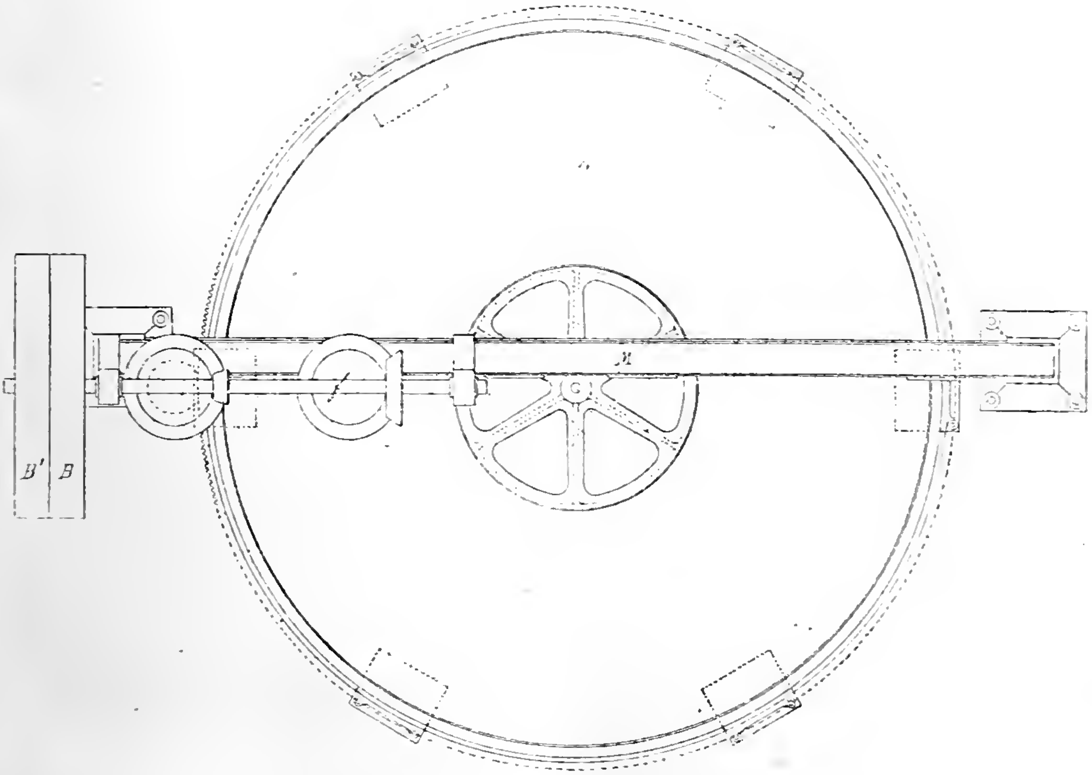

FIG. 2.

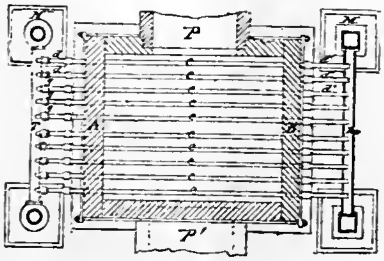

FIG. 10.

To this end the oxychloride, after remaining for some time in the boxes mentioned in the preceding operation, is crushed in a special apparatus consisting of cylinders bristling with diamond points. In passing between these cylinders the material is broken to pieces of the required size. It then falls into a rotary sieve, which separates from it all that can pass through a metallic cloth of which the threads are 5 millimetres apart. That which passes through this sieve constitutes the powder of oxychloride spoken of above. This dust can be either dissolved in HCl with magnesia in the first operation, or be reintroduced into the operation of preparing the oxychloride. We have succeeded in reducing the proportion of dust to 20 per cent. of the total weight of oxychloride.

FOURTH OPERATION.—DRYING THE OXYCHLORIDE OF MAGNESIUM.

The operation of drying previous to decomposition is necessary, because in the decomposition of the oxychloride by heat and air a larger quantity of free chlorine and a smaller quantity of hydrochloric acid result: 1st. If the material to be decomposed contains less water; and 2nd. If the decomposition is performed at a higher temperature. The previous drying is necessary for the realisation of the first condition. It is indirectly necessary for the realisation of the second condition, because the less water the material contains the less will it lower the temperature of the decomposing furnace.

Whereas chloride of magnesium containing six equivalents of water cannot be dried even partially without a large quantity of HCl being disengaged, the oxychloride can be made to lose a considerable quantity of water without the escape of more than a small portion of HCl. However, the desiccation must not be carried on at a temperature above 250° to 300° C. The only practicable means of drying the oxychloride therefore is to submit it to the action of a current of hot gases. The necessity of avoiding the formation of dust during the operation made it impossible to use the mechanical agitator for exposing the surfaces of the pieces of oxychloride to the current of hot gases. We have therefore adopted a system of working which consists in making a train of wagonettes with shelves one above the other, on which the oxychloride is spread in layers of 5 to 6 centimetres thickness, circulate in a flue in a direction opposite to that traversed by the hot gases.

The apparatus in and by which the drying of the oxychloride is effected is shown in Figs. 3 and 4 of the accompanying diagrams. Fig. 3 is a cross section of the flue or tunnel of brickwork through which the trucks filled with oxychloride pass. Fig. 4 is a longitudinal section of the said flue and trucks. The flue is furnished at its ends with the locks A, B, which permit trucks to enter and leave without opening direct communication between the interior of the flue and the atmosphere. To introduce a truck, the door *a* is opened, and is shut again after the truck has been put in the lock. The dampers *c* and *d* are then lifted, and by means of the pusher rack G the truck is made to advance into the flue. Having crossed the space separating it from truck No. 10, it pushes this truck and the whole train forward, itself occupying the place of No. 10, and No. 1 being pushed partly into the exit lock B. No. 1 is now drawn into the lock B by the hook D worked from outside The damper *d* is then shut, the door *b* opened and the truck withdrawn by hand. The hot gases enter the tunnel by the pipe M, and leave it by the pipe N. It may be produced in any manner, but it is important that its temperature should not exceed 300° C. Filling the trucks is a somewhat difficult operation, for it is necessary that the oxychloride should be spread in regular layers on each of the seven shelves of the trucks. We have succeeded in filling rapidly by means of the apparatus shown in Fig. 5. This apparatus consists of three parts:—1. A measurer A formed of seven equal spaces corresponding to the seven shelves of the truck. The bottom of each of these spaces is shut by an inclined door *a*, furnished with a lever. The seven levers are jointed to a connecting rod B, which is worked by a screw, two bevelled wheels and a hand wheel C, so that all the seven doors are shut or opened simultaneously. 2. Below the measurer is a sort of hopper D, also divided into seven compartments and mounted on wheels. 3. Under these two parts, and on a level with the drying apparatus, is a reversible frame E, on which the truck to be loaded is placed. In the drawing, this frame and a truck is represented as overturned—*i.e.*, in the position in which it should be to be loaded. Before being put in this position, the truck is furnished with a series of sheet-iron diaphragms, *d*, to limit on each side the thickness of the oxychloride. Two of the diaphragms are placed on each shelf, being introduced endwise by making them slide in like drawers. At the bottom end of the reversible frame are two rails R, on which the truck rests. These rails are supported by levers *f* and *g*, by which the truck can be raised so as to bring it against the top end of the reversible frame. The levers *f* and *g* are worked by the larger lever G, which is itself worked by the screw H and the crank M. The diaphragms are fixed by screws *n*, whose heads press against the cross-bars *o*, which form part of the diaphragms. The reversing movement is effected by the toothed wheel, pinion and crank shown by the dotted lines. When the diaphragms have been placed as described, the frame is reversed and the hopper D brought over the truck. The measurer having been filled with oxychloride, the wheel C is turned, opening the doors *a* and letting the material drop, which, being guided by the hopper D, descends into the spaces between the shelves and the diaphragms. The reversible frame is then brought to its normal position, the diaphragms are removed, and the truck is ready to enter the drying apparatus. The following table will indicate the results of this process of desiccation:—

TABLE A.

RESULTS OF DRYING OXYCHLORIDE OF MAGNESIUM.

Equivalents of MgO per Equivalent of Cl in the Oxychloride.		Percentage of Cl in the Oxychloride.		Percentage of H_2O in the Oxychloride.		Cl Lost per Cent. of the Cl in the Wet Oxychloride.	H_2O Lost per Cent. of Water in the Wet Oxychloride.
Wet.	Dry.	Wet.	Dry.	Wet.	Dry.		
1·333	1·359	26·73	32·89	44·27	30·89	1·12	44
1·391	1·511	25·91	32·05	44·97	29·81	4·67	49
1·343	1·531	25·80	32·73	45·93	27·97	7·43	55
1·346	1·511	26·16	33·30	45·16	27·09	6·60	57

During this operation the oxychloride loses 60 to 65 per cent. of its water; at the same time it disengages in the state of HCl from 5 to 8 per cent. of its chlorine. The dried product is therefore richer in magnesia than the original material. Thus 100 of original oxychloride, of which the analysis is given above under "Preparation of Oxychloride of Magnesium," is reduced by drying to 73·36, formed of:—

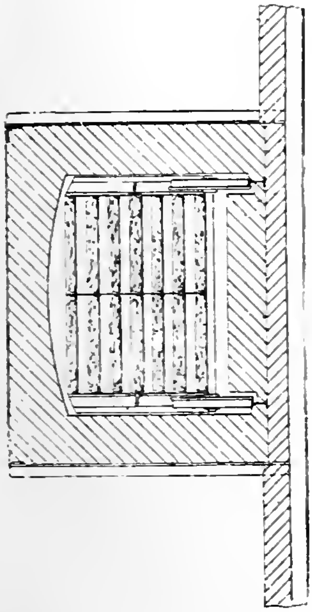

Fig. 3.

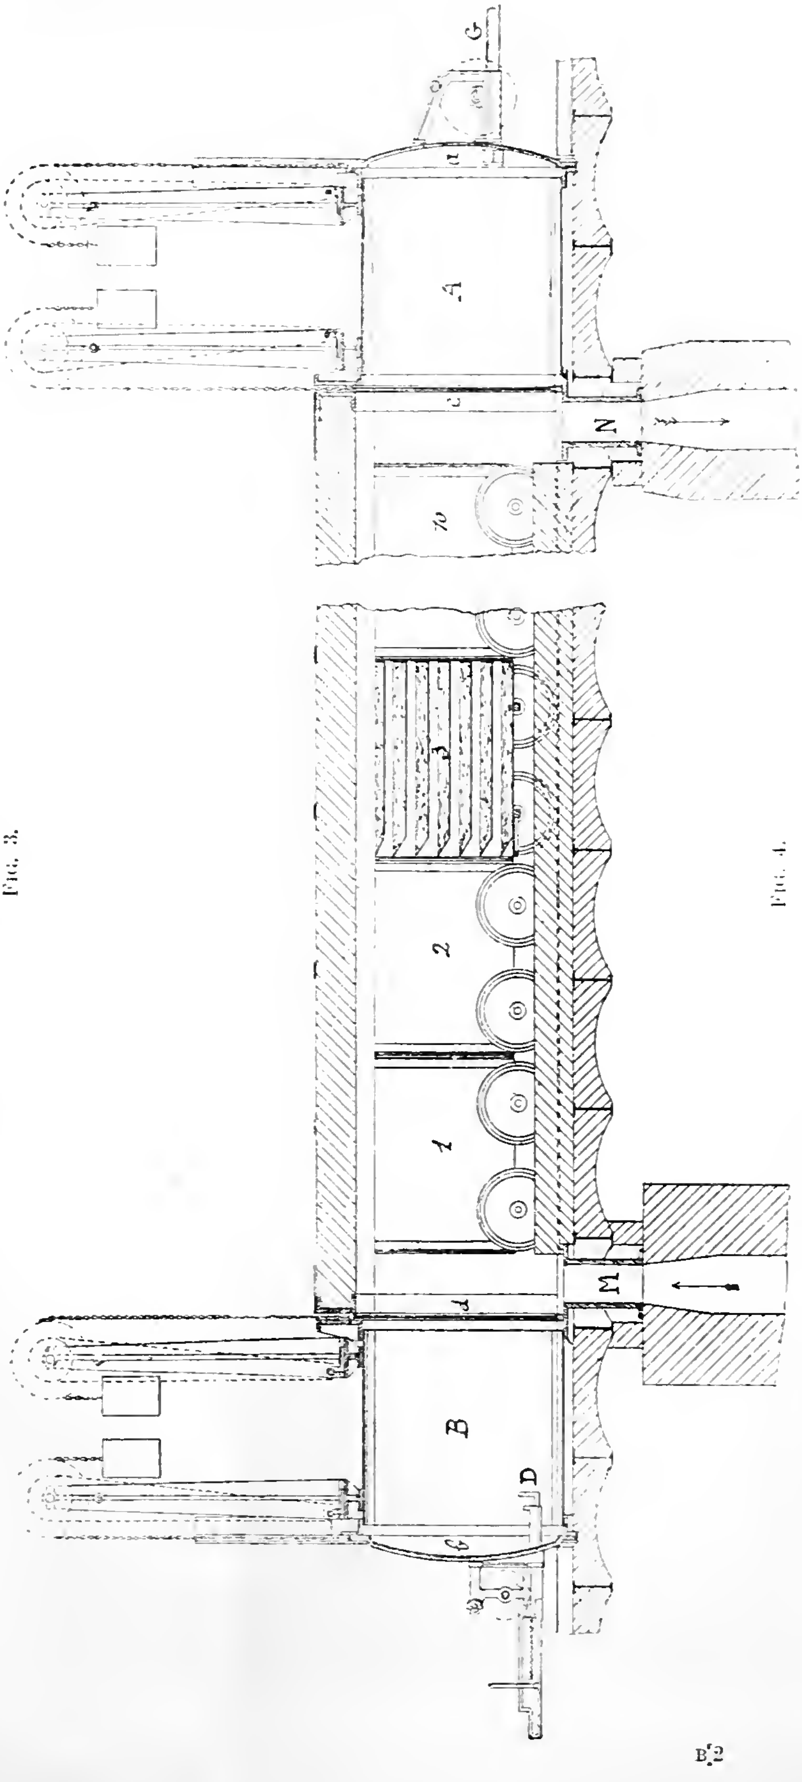

Fig. 4.

Impurities	4·00	
Water	15·86	
$MgCl_2$	32·69	($Cl = 24·43$)
MgO	20·81	
	73·36	

and of which the centesimal composition is:—

Impurities ..	5·47	
Water	21·62	
$MgCl_2$	41·45	($Cl = 33·30$ per cent.)
MgO	28·36	= 1·511 equivalents per $MgCl_2$.
	100·00	

As 100 parts of oxychloride before drying contained of Cl 26·16, and have been reduced to 73·36 parts containing Cl 24·43, the drying has caused a loss of Cl 1·73. Say that 6·6 per cent. of the Cl put in work have been lost in this operation. This loss will hardly exceed 8 per cent. We shall have occasion to speak of this further on.

FIFTH OPERATION.—DECOMPOSITION OF OXYCHLORIDE OF MAGNESIUM

The first idea which occurs to one's mind for carrying out this operation is to employ an apparatus analagous to a retort, heated externally, into which the dried oxychloride should be charged and air passed through. But this method of working was impracticable for several reasons, the chief one being that both magnesia and oxychloride of magnesium are very bad conductors of heat. Supposing a retort of practical size and dimension filled with oxychloride of magnesium, it would require a considerable time and an enormous quantity of fuel to bring the centre of the mass to a red heat. And not only would there be a great expenditure of fuel, but the operation would be executed under extremely bad conditions from the point of view of getting free Cl. Experience has proved that the proportion of free Cl driven off is always greater and the proportion of HCl always smaller the more rapidly the oxychloride is brought to the maximum temperature. For these reasons, and for others (for instance, the porosity of refractory retorts), the apparatus shown in Figs. 6, 7 and 8 was adopted instead of the retort. This apparatus and the method of working it may be briefly described as follows:—

Fig. 6 shows a vertical section, alike of the furnace proper and of the movable regenerative burner. Fig. 7 shows a horizontal section, alike of the furnace proper and of the said movable regenerative burner. The upper part of this section is taken along the line C, D, Fig. 1, and the lower part of it along the line E, F, Fig. 6. Alike in Fig. 6 and in Fig. 7, the movable regenerative burner is shown in the position, in relation to the furnace proper, which it occupies during the operation of heating up the working chambers of the latter. Fig. 8 shows a vertical section of the furnace proper, taken at right angles to the section shown in Fig. 6. A, A, A, A, Fig. 8, are four narrow decomposing chambers, having very thick walls. The upper extremity of each chamber A opens into the combustion chamber, B. The lower extremity of each chamber A communicates with one of the four horizontal channels, *a, a, a, a*. D, Fig. 6, is the movable regenerative burner. It consists of a system of cast-iron pipes, contained in an envelope of masonry, which envelope of masonry is encased with iron plates, and securely armatured. The cast-iron pipes are of rectangular section, and each of them is divided, by two vertical partitions, into three compartments, *i, o, u*. The central compartments, *o, o, o*, etc., convey gaseous fuel into the combustion chamber B, and the side compartments *i* and *u*, convey air into the combustion chamber. The gaseous fuel is supplied by the main pipe upon which is the valve N, Fig. 7, from which main pipe it passes by the pipes V and C, Fig. 7, into the flue C, Fig. 6, from which flue C it enters the compartments *o, o, o*, by apertures at the bottom of those compartments. Having reached the upper extremity of the compartments *o, o, o*, the gaseous fuel issues into the combustion chamber B, by the small pipes *d, d, d*, Figs. 6 and 7. The air which is to burn the gaseous fuel enters at the bottom of the compartments *i* and *u*, and, having risen to the upper extremity of those compartments, issues into the combustion chamber by the wide flat pipe T, Fig. 6. It will be seen from Fig. 6 that the small pipes *d, d, d*, pass through this wide flat pipe T, and that the small pipes *d, d, d*, are a little longer than the flat pipe T. The pipe V, Fig. 7, is fixed to the main pipe on which is the valve N. The pipe C, Fig. 7, is fixed to the movable regenerative burner. When the movable regenerative burner is in the position, in relation to the furnace proper, in which it is shown in Figs. 6 and 7, the pipe C communicates with the pipe V, at the point U, Fig. 6. The joint at U is one which can be readily made and readily unmade. From the combustion chamber B, products of combustion enter the narrow working chambers, A, A, A, A, by the upper extremity of each of them. After traversing these chambers downwards, they pass off, by the four horizontal channels *a, a, a, a*, into the movable regenerative burner. Following the direction of the arrows in Fig. 1, they pass upwards through the flues Z, Z, Z, Figs. 6 and 7, and then travel downwards, circulating round the rectangular cast-iron vertical pipes which have been described, and passing between those rectangular pipes, and then passing off from the burner by the pipe P, Figs. 6 and 7, which conveys them to the flues G, Fig. 6. In thus passing downwards through the movable burner, they heat the gaseous fuel which is passing upwards through the compartments *o* and the air which is passing upwards through the compartments *i* and *u*. They are then conveyed to the apparatus employed for the drying of the oxychloride. The pipe P, which is fixed, communicates with the flue by which products of combustion pass off from the movable burner by the piece Q, the lower part of which fits into the upper part of the pipe P, in such manner that the piece Q can be raised or lowered by the lever S. It will be seen from Fig. 6 that the whole regenerative burner is mounted on wheels. When the burner is in the position in relation to the furnace proper, in which it is shown in Figs. 6 and 7, the wheels of the movable regenerative burner stand on rails upon a truck K, K, Figs. 6 and 7. This truck also stands on rails. When the truck is drawn a short distance from the furnace proper the rails on the truck K become in such a position in relation to other rails, one of which is shown at *r*, Fig. 6, that the burner can be transferred to other rails, and drawn along them on to another truck installed opposite another furnace. Thus, while oxychloride of magnesium is being heated in a current of air in one furnace, the movable regenerator can be employed to heat up the decomposing chambers of another similar furnace. The working of the apparatus will now be easily understood. When the four working chambers A, A, A, A, have been heated to a sufficient temperature, the first step is to close the valve N, Fig. 7, and so to cut off the supply of combustible gas to the movable regenerative burner. The pipe C, Figs. 6 and 7, must then be disconnected from the pipe V, Fig. 7, the pipe P must be lowered, and then the truck on which the whole regenerative burner is supported must be drawn away from the furnace proper, until the wheels of the burner are opposite the rails, one of which is marked *r* in Fig. 6. The openings by which products of combustion have entered the working chambers must now be closed by the door E, Fig. 6, and the

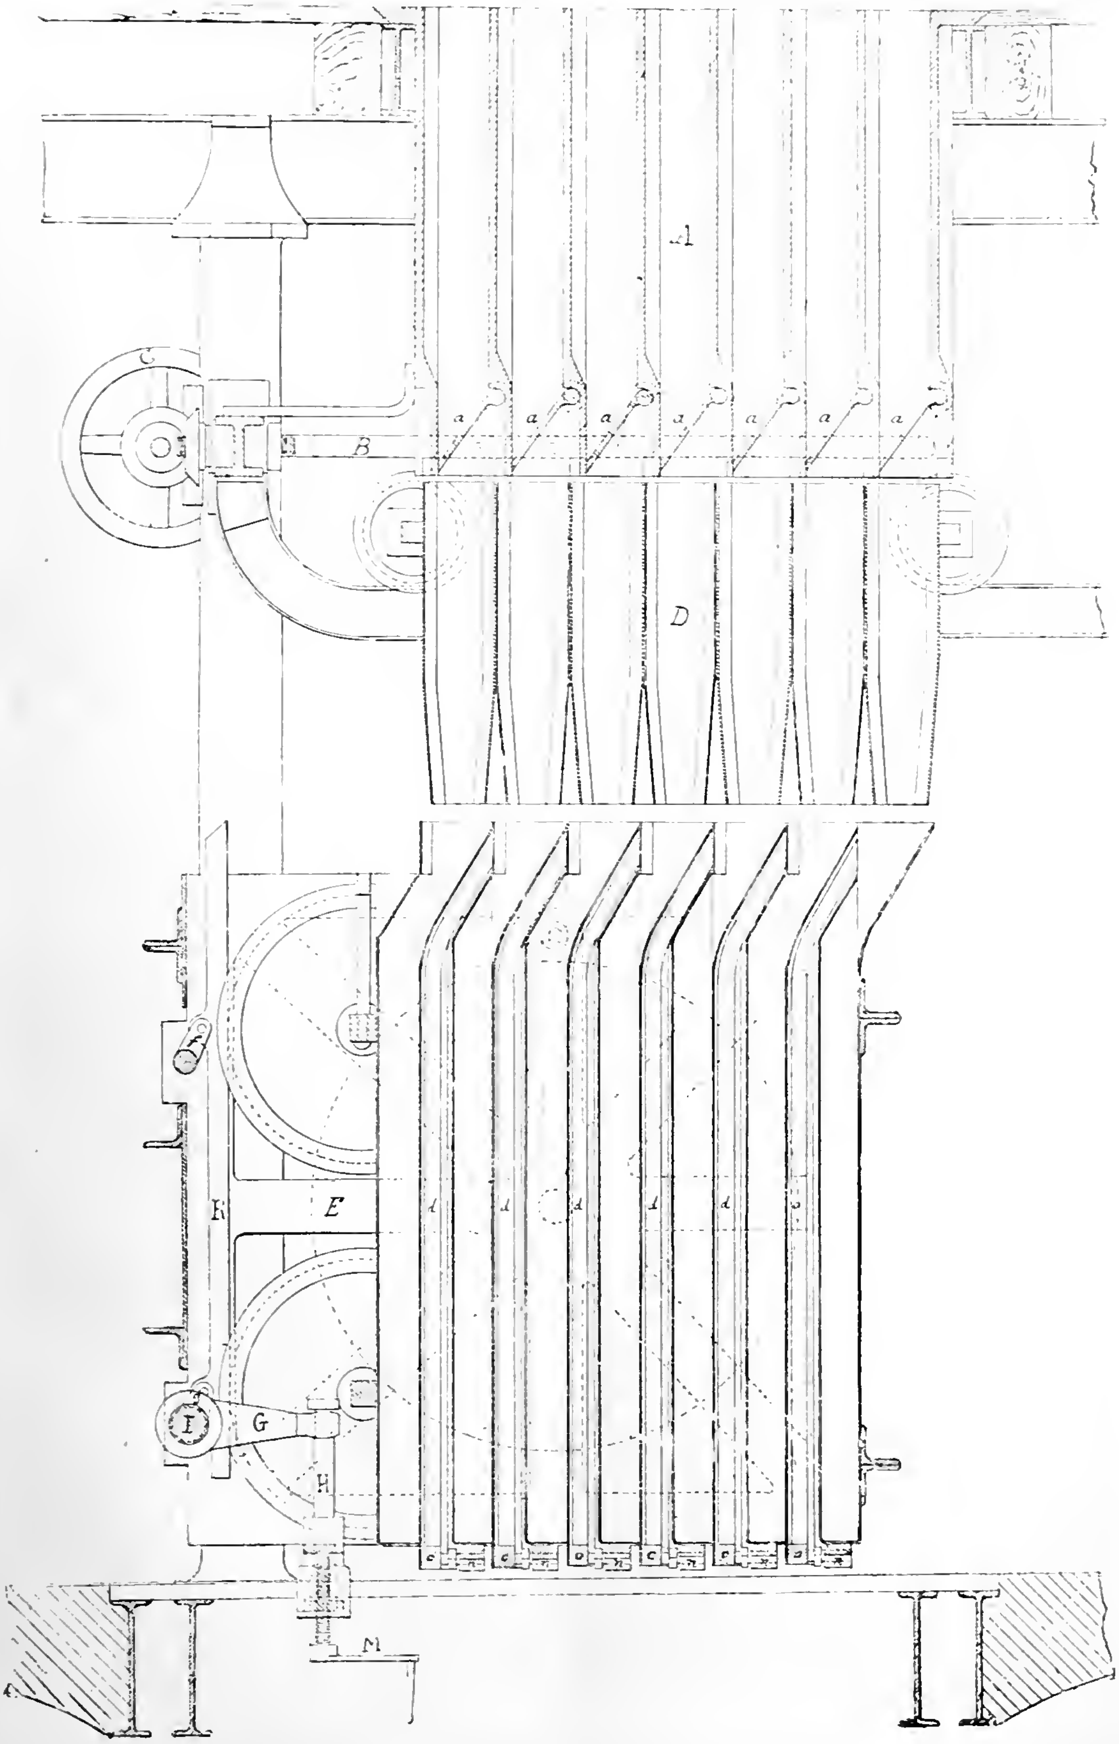

Fig. 5.

opening by which those products of combustion have passed off from the working chambers must be closed by the door F, Fig. 6. One door E and one door F suffice for the whole furnace. The doors E and F are hung on hinges; and when they are in position to close the openings to which they correspond, they are pressed tightly against their seats by screws. The decomposing chambers A, A, A, A, are charged with oxychloride of magnesium, in small pieces, from a tip-waggon charged therewith which has been previously brought into position on the top of the furnace. The oxychloride enters the decomposing chambers by the opening H, Figs. 6 and 8. The cover or door which closes this opening is seen in Figs. 6 and 8, but is not marked with any letter. This cover having been removed, a hopper is brought over the opening H, and oxychloride is then poured into the hopper, whence it falls into the chambers A, A, A, A. The door or cover of the opening H is then rapidly replaced and air is admitted into A, A, A, A, through apertures in the door E. The oxychloride rapidly becomes heated by absorption of some of the heat previously stored up in the walls of the chambers in which it is contained, and there passes off from those chambers a mixture of gases and vapours containing both free chlorine and vapour of hydrochloric acid. This mixture of gases and vapours passes off from A, A, A, A, by the horizontal channels *a*, *a*, *a*, *a*, into the vacant space between the masonry of the furnace and the door F, and then passes by the channel *l*, Fig. 7, into the pipe *m*, Figs. 7 and 8. From the pipe *m* the mixture of gases and vapours is conveyed to apparatus for condensing out of it vapour of hydrochloric acid, and what passes off from that apparatus then goes on to apparatus for the absorption of chlorine. The air which enters the chambers A, A, A, A, through apertures in the door E, is drawn in by means of an aspirator. When the decomposition of the oxychloride has proceeded sufficiently far, the admission of air into the working chambers is arrested, the door F is opened, and the residual oxide contained in the chambers A, A, A, A, is discharged. That residual oxide is drawn out of the horizontal channels *a*, *a*, *a*, *a*, by means of a suitable rake. When the residual oxide has been completely discharged the cover of the opening H is replaced, and then the door E having been opened, the movable regenerative burner is brought back into the position in which it is shown in Fig. 6, and the decomposing chambers of the furnace proper are then heated up again for another operation. Table B gives the results of several operations of decomposition. Fig. 11 shows the result of a special operation made at my request with a view to determining the rate of evolution of the chlorine.

Of course in actual working care would be taken to make the operations in the various decomposing furnaces overlap one another, so as to maintain the percentage of chlorine at a fairly constant average. The form of the curve obtained in this experimental operation suggested to my mind that the reaction was a reversible one: that is to say that when, as in this case, magnesium chloride is treated by oxygen it forms magnesium oxide and chlorine, and when the resulting magnesia is treated by chlorine it gives chloride of magnesium and oxygen. In order to arrive at an accurate understanding of the matter I determined to make a series of experiments myself. First, however, I looked up the literature of the subject in the best textbooks, but could find no mention of it. But when I went back to Davy I found that he did know that magnesia treated by chlorine gives chloride of magnesia + oxygen, and I found further that Graham knew that chloride of magnesia + oxygen yields magnesia + chlorine. However, all these facts appear to have been eliminated from our modern manuals. We will now make an experiment to prove this interesting reaction. My assistant has here a porcelain tube containing anhydrous oxychloride of magnesium. If he slowly passes through this tube a current of oxygen we shall collect at the other end an equivalent quantity of chlorine. If he now reverses the operation, substituting a current of chlorine, we shall obtain as the product a continuous current of oxygen. Therefore the reaction is a balanced or reversible one. Calling one end of my apparatus A and the other end B, I found that by passing oxygen from A to B, I obtained from 82 to 77 per cent. of chlorine, and by reversing the current and passing it from B to A I got 75 to 78 per cent. in the resulting gas. Whichever way I worked the result was practically the same, 75 per cent. of chlorine and 25 per cent. of oxygen. Then, by passing chlorine from A to B, I obtained 22 to 28 per cent. of oxygen, and from B to A 26 to 24 of oxygen in the gaseous mixture. The impression I had formed from the curve given in the above diagram was therefore amply confirmed. My theory of the decomposition which goes on in the furnace is that,

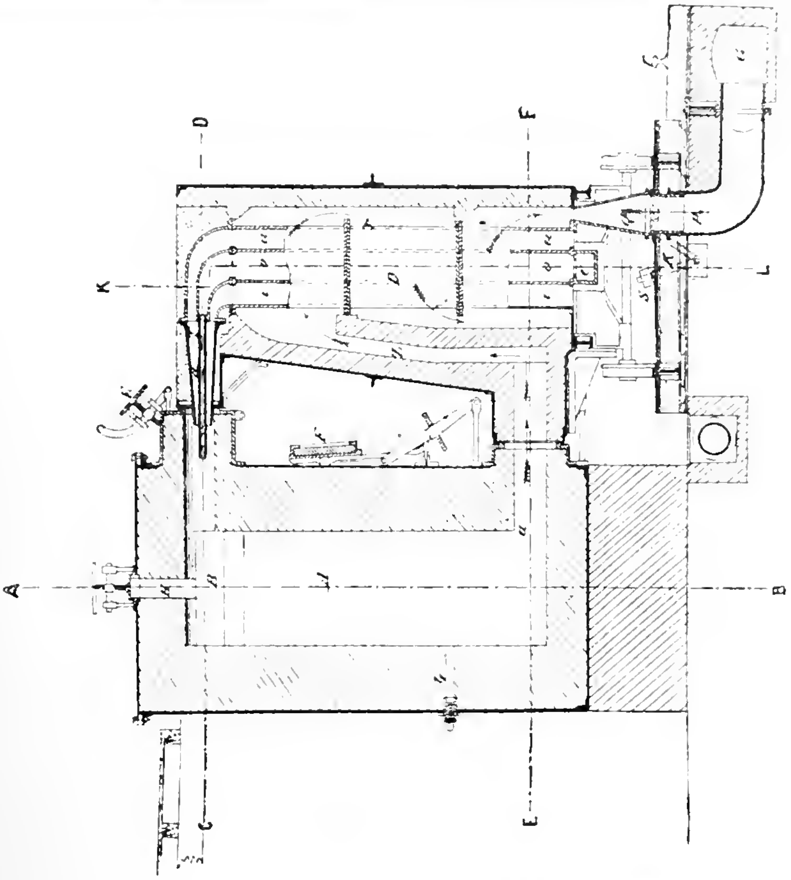

Fig. 6.

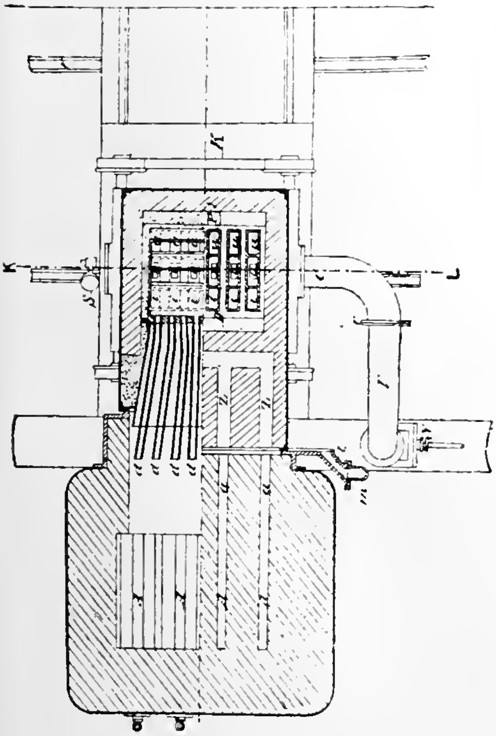

Fig. 7.

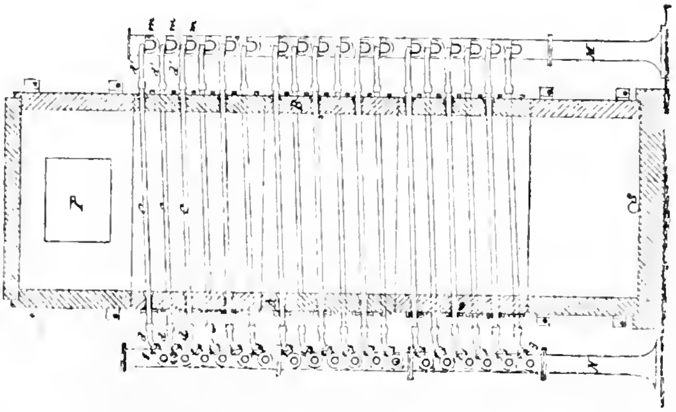

Fig. 9.

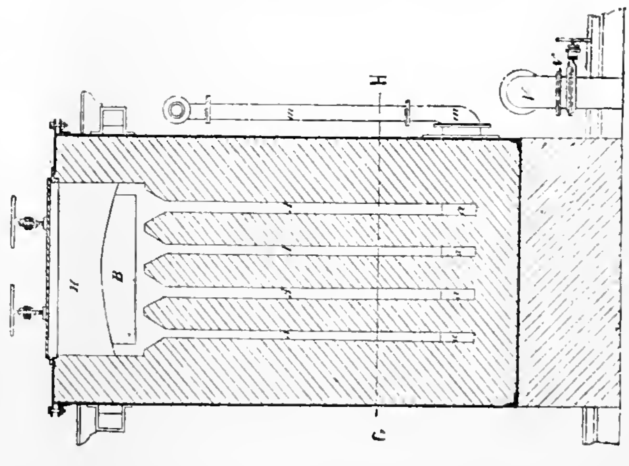

Fig. 8.

in the first stage, there is a rapid evolution of steam; the steam decomposes a portion of the magnesium chloride, producing hydrochloric acid, which passes off with the vapour of water. What remains is anhydrous magnesium chloride and magnesia, and this mixture then undergoes the reaction which we have just seen by the action upon it of atmospheric oxygen. I shall pursue these experiments further, because it will be interesting to know whether the decomposition will vary with a varying pressure of oxygen. Finding in my first experiment that three-fourths by volume of the original oxygen was replaced by chlorine I inferred that three-fourths of the oxygen contained in the air would be the proportion which would replace the chlorine at the temperature attained—viz., a full red heat, or nearly 1000° C. I therefore looked for 15 to 18 per cent. of chlorine when I used air; instead of which I got 30 per cent., showing a nearly complete absorption of the oxygen.

The products of the decomposition have to be drawn off from the furnace by means of a diminished pressure steadily maintained. For this purpose M. Pechiney employs an aspirator consisting of two small gasometers of cylindrical form, plunging in a concentrated solution of chloride of calcium. This solution is used rather than pure water, because Cl is nearly insoluble in it. These cylinders have a regular vertical movement, alternately up and down. A tube traverses the bottom of the vat which contains the solution of $CaCl_2$, and rises in the interior of the cylinder to a height superior to that which the liquid attains. When the cylinder rises it causes aspiration by means of this tube, and when it descends it drives back, through a tube, the gases with which it was previously filled. The said tube is connected outside the cylinder with two other tubes, one of which is fixed to the apparatus through which pass the aspirated gases, the other being fixed to the apparatus through which pass the rejected gases. Each of these new tubes is closed alternately by valves worked by the movement of the apparatus itself; that is to say, when the cylinder ascends the valve of the suction tube is opened and that of the ejecting tube is closed, and when the cylinder descends the valve of the ejecting tube is opened and that of the suction tube is closed. The two cylinders of the pump in question are suspended at the extremities of a balance, so that while one is rising the other is falling. The action of aspiration and rejection is therefore nearly continuous and regular. The aspirator is not in immediate connexion with the decomposing furnace, but acts through:

1. An ordinary HCl condensing tower.
2. A number of sandstone bonbonnes.
3. A glass tube refrigerator.

This refrigerator consists of a stone tower, of square or rectangular horizontal section, in the interior of which tower are arranged, in an inclined position, glass tubes, through which cold water is kept flowing. The said stone tower, in the interior of which the said glass tubes are placed, may be constructed after the same manner as the towers in which the vapour of hydrochloric acid which is generated in the first stage of the manufacture of soda by the Leblanc process is usually condensed. This tower is shown in vertical section in Fig. 9 and in horizontal section in Fig. 10. Two opposite sides of the said tower are each pierced with holes. These holes should preferably be arranged in horizontal rows, those of any one row except the lowest being, not immediately above the holes in the row beneath it, but above the spaces between the holes in the row immediately beneath. In Figs. 9 and 10 the two sides of the tower which are so pierced with holes are marked A and B. In Figs. 9 and 10 the glass tubes are marked *c*, *c*, *c*, *c*. One extremity of each of these glass tubes protrudes through one of the holes in the A side of the tower, and its other extremity protrudes through the corresponding hole in the opposite or B side of the tower. On the A side of the tower (which may of course be whichever of its four sides is most convenient in each case) the protruding extremity of each glass tube is connected by a piece of caoutchouc tubing, or other equivalent appliance, marked *d*, *d*, *d*, in Figs. 9 and 10, with one of the tubes or pipes some of which are marked T. These tubes T may be of iron or other convenient material. Water passes into these tubes T from the hollow column N, and then from the tubes T into the glass tubes *c*, *c*, *c*, *c*. On the B side of the tower the protruding extremity of each glass tube is connected with a piece of caoutchouc tubing, or other equivalent appliance marked d^1, by which, in each case, water which has entered one of the glass tubes from the hollow column N by one of the pipes T, and has traversed the glass tube, passes from that glass tube and is discharged into one of the gutters or conduits *m*, *m*, *m*. From the gutters *m*, *m*, *m*, the water discharged from the glass tubes passes away by the hollow column M. In order that the glass tubes *c*, *c*, *c*, *c* may not be liable to break, it is necessary that they should be kept always full of water. This result may be secured by slightly inclining the glass tubes, as in Fig. 9, placing that extremity of each of them by which water enters it a little lower than that extremity of it by which water is discharged from it. When the mixture of vapours and gases which the apparatus is employed to cool is one from which an acid liquor condenses during the operation of cooling it, this acid liquor will condense upon the glass tubes, and will run along each tube towards its lower extremity, being the extremity of it which is at the A side of the tower, or at the side of the tower at which the cooling water enters the glass tubes. It is, therefore, necessary that, at that side of the tower, the joint between the glass tube and the stone through which it passes should be perfectly tight. It will be seen that upon that extremity of the glass tube *c* which protrudes through the A side of the tower there is placed a short piece of caoutchouc tubing upon which is a caoutchouc flange, which flange comes in contact with the face of the stone through which the tube passes, and is pressed tightly against the face of that stone by the tubular flange of the gland *n*, *n*, that tubular flange of the gland *n*, *n*, being pressed tightly against the annular flange of the piece of flanged caoutchouc tubing *i*, *i*, by means of screws passing through the annular flange of the gland *n*, *n*, and working into the iron bar or band R, R. The joint between the other extremity of each glass tube *c* and the stone through which it passes on the B side of the tower may be made simply by means of any cement unattackable by acids. The gas or vapour to be cooled by this apparatus should preferably enter near the top of the tower, for example at P, Figs. 9 and 10, and the cooled gas or vapour should preferably pass off from near the bottom of the tower, on the opposite side of it, as at P^1, Fig. 10. Any liquid condensing in the tower will pass out of it by the aperture S, Fig. 9. It will be evident that if one of the glass tubes, *c*, *c*, *c*, happens to break, the broken tube can be removed and a new one put in its place very readily, and without stopping the working of the apparatus. The fact that a tube has broken will be perceived by an increase in the quantity of liquid discharged from S, and which tube it is which has broken will be indicated by water ceasing to issue from that extremity of the broken tube which protrudes through the B side of the tower. The cock *g* of that tube may then at once be closed, and the broken tube be removed, and a new one substituted for it, without interrupting the working of the apparatus.

It is this last apparatus which is in immediate connection with the decomposing furnace by means of a pipe. The gases leaving the decomposing furnace by the pipe M pass, by another pipe, into the glass tube refrigerator. There they are condensed. From the refrigerator they pass on through a series of sandstone bonbonnes and, lastly, through a condensing tower. In their passage above described the gases have been deprived of the whole of their HCl, and they now enter the cylinders of the aspirator as a mixture of air and chlorine gas. It is this gaseous mixture which the cylinders drive into special apparatus wherein they are brought into contact with milk of lime, which is gradually transformed into a mixture of chlorate of lime and chloride of calcium. It is by the volumetric measurement and the analysis of this liquid that the production of chlorine is calculated.

The hydrochloric acid condensed in the refrigerator, in the bonbonnes, and in the tower, is all mixed in a single reservoir, and yields an acid averaging about 12° B. It would be possible to obtain a much stronger acid, thus :—The vapour which at the beginning of the operation is condensed in the glass tube refrigerator, contains an enormous proportion of water, and only a small proportion of HCl. But later on the proportion of water diminishes greatly, while the proportion of HCl does not diminish. It would be possible to condense the relatively strong gaseous HCl in the weak aqueous acid of the refrigerator and the condensing tower. This has not yet been done, but it is a course which would suffice to bring the whole of the aqueous HCl of the process to a strong degree. For proof of this it will be sufficient to compare, in the figures which will be given later on, the relative quantities of HCl gas and vapour of water which are disengaged during the decomposition.

The decomposition of oxychloride of magnesium produces, as we have just seen, free chlorine and aqueous hydrochloric acid. The proportion of the Cl given off in the free state to that disengaged as HCl is as 53 to 47. There remains in the residues a quantity of Cl equal to about 15 per cent. of the total Cl charged into the furnace.

Consequently there is obtained per 100 of chlorine charged :—

Cl remaining in the residues	15·00
Free Cl	45·23
Cl as HCl	39·77
	100·00

Or, as these 100 of chlorine charged arise from 107 of Cl commenced with [there being a loss of 6·60 per cent. during the operation of drying], 100 of original chlorine would be accounted for thus :—

Cl lost in drying	6·60
Cl remaining in the residues	14·00
Free Cl	42·25
Cl as HCl	37·15
	100·00

If, besides this, we admit a loss of 5 per cent. of Cl during the various manipulations, especially in emptying the tanks in which the magnesium chloride is clarified, a loss which, if taken at 5 per cent., is certainly exaggerated, the account of each 100 of Cl put in work would be

Cl lost absolutely	In the various manipulations	5·00	11·27
	In drying	6·27	
Cl entering again into the process	Remaining in the residues	13·30	48·59
	Condensed in the state of HCl	35·29	
Cl produced in the free state			40·14
			100·00

Consequently, to produce 40·14 of free Cl one must consume 100—48·59 or 51·41 of Cl. The result in free Cl of the Cl entering the process is therefore 78 per cent.

One can see at a glance that this result can be improved only by succeeding in one or more of three things. :—

1. In diminishing the loss of Cl.
2. In increasing the proportion of free Cl yielded.
3. In diminishing the quantity of Cl remaining in the residual magnesia.

It is probable that the process will improve in all these various ways. And to produce this effect one means will suffice—viz., the improvement of the heating of the decomposing furnace. At present we obtain therein a mean temperature of about 1000 degrees C. It is necessary to greatly increase that temperature.

The magnesia when it is taken out of the furnace is, firstly, cooled by putting it in a vessel provided with a mechanical agitator, this vessel itself being placed in another vessel, and cold water being circulated through the space between the two. The MgO having a very weak capacity for heat is quickly cooled. The mechanical cooling is necessary, however, because MgO is an extremely bad conductor of heat. When the magnesia is cooled sufficiently it passes into a rotary sieve, which separates it into two parts :—

1. The more important part (about ⅘), which passes through the sieve as a fine powder, being almost entirely decomposed, containing hardly 4 per cent. by weight of Cl.
2. The less important part (about ⅕) which cannot pass through the sieve. This latter is oxychloride hardly at all decomposed, retaining no water, it is true, but containing much Cl, sometimes as much as 40 per cent. by weight. *This portion of the residue is at once mixed and re-charged* with oxychloride from the fourth operation.

It will be seen, therefore, that when native chloride of magnesium is treated, the magnesia which will be drawn out will be the *fine* magnesia, containing not more than 4 per cent. by weight of Cl—a small proportion considering the low equivalent of magnesia.

At Stassfurt, the working of 100 parts of $MgCl_2 6H_2O$ (containing, say, 35 parts of Cl) will yield a residue of about 20 parts of MgO. At the rate of 4 per cent. these 20 parts of MgO will contain 0·8 part of Cl, or only 2·3 per cent. of the total chlorine entering the process. Such a loss of Cl will be insignificant.

The present installation at Salindres comprises two furnaces of nine chambers each. These chambers are each 3 metres high, 1 metre long, and 0·08 metre wide. These two furnaces, heated alternately by a single regenerative burner, constitute a unit. It has been seen that such a unit should produce per 24 hours 1000kilos. of free Cl with three operations to each furnace, say six operations in all, or about 170kilos. per operation. Instead of which, at present, owing to the insufficiency of the heating apparatus, we can make only two operations in each furnace, or four operations in all per 24 hours, which give, according to the heat of the furnaces, from 180kilos. to 190kilos. of free Cl each. There is obtained, therefore, per 24 hours from 720 to 760kilos. of free Cl. The improvement of the heating of the furnaces would considerably change all the results. Indeed, if the furnaces could be made considerably hotter, one might dry the oxychloride a little less than at present without fear that the increased humidity of the material charged would inconveniently lower the temperature of the furnace. And as it is the expulsion of the last portions of the water driven off which causes the principal loss of HCl in the fourth operation, it will thus be seen that that loss might be considerably reduced. Moreover, with hotter furnaces, the quantity of total chlorine disengaged (Cl + HCl) would be greater, or in other words the decomposition would be more complete. And, lastly, with hotter furnaces, the decomposition would be more rapid, so that at least five operations might be made per 24 hours instead of four, as at present, and that without proportionately increasing labour or the consumption of coal. In a word, if a higher temperature is obtained in the furnaces, the quantity of chlorine will be greater, and the cost per ton for producing it will be less.

It has been said above that the respective quantities of steam and gaseous HCl which come from the decomposing furnace are such as not to prevent the obtainment of a concentrated aqueous HCl. In fact, for every 100 of chlorine charged there is obtained a quantity of Cl in the state of HCl=to 39·77. And it is shown above that in the dried oxychloride 33·3 of Cl are accompanied by 21·62 of water. That is to say, 100 of Cl charged are accompanied by

64·8 of water	64·8
But the above 39·77 of Cl have been disengaged in the state of HCl holding a quantity of water=	10·0
The quantity of water disengaged is thus only	54·8

and this quantity is not sufficient to condense the 39·77 of Cl in the state of HCl—which in reality represents about 41 of HCl.

Having now described the process itself, let us consider the question of cost of production, and in that respect compare it with the old Weldon process. The latter was essentially a cheap method. The plant required for it was not an expensive one, nor did it involve any great cost for repairs. The plant for the new process is more complicated, and consequently more expensive. On the other hand, the results obtained have increased the confidence which M. Pechiney has always had in the process, and have decided him to commence at once the erection of an industrial installation to work on a scale of 6000kilos. of free chlorine per day. Speaking of the small experimental plant which he has been working since last July, M. Pechiney says :—

1. We produce at the present time from 720 to 760kilos. of chlorine per 24 hours, at the following cost :—

		Francs.
Coal for the drying and decomposing furnaces	3300kilos.	
Coal for mechanical work	500 „	
Coal for concentrating $MgCl_2$	500 „	
	4300kilos. @ 12fr.	51·60
Labour		74·00
Repairs		20·00
Loss of magnesia (?)		5·00
		150·60

Say for 1000kilos. at the most 209·20fr.

2. If in working the one unit we succeed in producing 1000kilos. of Cl per day instead of 740kilos. as at present, by getting a higher temperature and a more rapid decomposition in the furnaces, the only expenses which would be increased (but which would certainly not be increased proportionately) would be those for fuel and magnesia. The other expenses would remain unaltered. The expenses for a production of 1000kilos. of Cl would then at the utmost amount to :—

	Francs.
Coal, 6000kilos. @ 12fr.	72·00
Labour	74·00
Repairs	20·00
Loss of magnesia (?)	7·00
Say for 1000kilos. of chlorine	173·00

3. The experience which we now have of the process, and certain improvements which we see our way to make in the heating of the decomposing furnace and in various points of detail, warrant us in expecting, with an installation producing 6000kilos. per 24 hours, the following cost of production per 1000kilos. of Cl :—

	Francs.
Coal, 1500kilos. @ 12·00fr.	18·00
Labour	75·00
Repairs	20·00
Loss of magnesia	5·00
Say for 1000kilos. of chlorine	118·00

It will be seen at once from these figures and from some which will follow, that the main expense of the process is for fuel, and that if fuel were as cheap in France as in England, M. Pechiney would be able to produce a ton of chlorine at the same working cost as he calculates it is now produced in England by the old Weldon process—viz., 94 francs. There is no doubt that the main feature of the new process is economy of hydrochloric acid ; for whereas the old Weldon process yields only 33 per cent. of the Cl entering into it, the process now under consideration yields 78 to 80 per cent. at least. Roughly speaking, therefore, the economy effected by it as compared with the old process, may be said to be the equivalent value of two tons of absolute HCl per ton of Cl produced. Now, Mr. Weldon has himself estimated the value of HCl. He says (this Society's Journal, 1883, p. 434) :—"HCl costs the Leblanc soda maker 36 per cent. of the total cost of the process by which he obtains it. The cost of that quantity of HCl, which is required by the present Weldon process for the manufacture of one ton of B.P., amounts to more than all the other items of the cost of that ton of B.P. put together. I believe M. Pechiney will eventually succeed in realising a cheap process which will diminish the present cost of B.P. for HCl by not less than two-thirds." He estimated the value of 27 per cent. acid to the Leblanc soda maker to be about £1 per ton, and he arrived at that value by taking the difference in the cost of producing a ton of soda by the Leblanc process and the ammonia process. That difference, he maintained, was the value to the Leblanc manufacturer of the quantity of acid which he produced in the making one ton of soda. It is incorrect to say that the value of HCl has diminished, though it is possible that the selling price of HCl has materially diminished. This decrease can be explained by the fact that the manufacture of B.P. having diminished by reason of an arrangement between the makers, there is a little more HCl for disposal. But this decrease in the selling price applies only to a certain limited quantity of HCl. The real value of HCl ought not to be expressed by the selling price of certain quantities of acid, but rather, as Mr. Weldon always maintained, by the difference between the cost price of ammonia soda and the cost price of Leblanc soda. Now, one ton of soda ash of 58 per cent. corresponds to about 2 tons 6cwt. of aqueous HCl of 28 per cent. If this latter is worth only 10s. per ton, there ought to be a difference of only 26s. per ton of 58 per cent. ash between Leblanc and ammonia soda. The difference is much greater than 26s., and must be nearly double that, say 50s. It cannot be much less than 20s. per ton. By finding the difference in the cost price of the two soda processes, I fix the value of HCl, and that difference is such as to bring the value of aqueous HCl of 28 per cent. to very nearly £1 per ton. Admitting, however, its value to be only 16s. per ton, that would bring the value of a ton of gaseous HCl to £2 16s.

It is possible, of course, that circumstances may be changed in the future—for example, by the recovery of sulphur; but that will be of no great importance. At present, the pyrites sulphur entering the Leblanc process at 3d. per unit, costs nearly 10s. per ton of 58 per cent. soda ash. If Mr. Chance succeeds in recovering sulphur at an average cost of 1d. per unit, the expense for pyrites will be lessened by two-thirds, or 6s. 8d. per ton of 58 per cent. soda ash. This would reduce the value of the 2 ton, 6cwt. of 28 per cent. HCl by 6s. 8d. in all, or say 2s. 6d. per ton.

It is therefore incorrect to say that the value of HCl has diminished in England during several years past. The value of HCl should increase in proportion as the selling price of alkali decreases. And for several years past the selling price of alkali has not ceased to decrease. The selling price of English soda ash and caustic soda is now 20 to 25 per cent. lower than it was in 1884. I admit, however, that this reduction is to some extent due to improvements in Leblanc plant, large furnaces, etc.

We have said above that for the English Leblanc manufacturer HCl gas ought to have a value of £2 16s. per ton. On the other hand the *probable* cost price of Cl per 1000kilos. at *Salindres* will be—

	Francs.
Coal, 4000kilos. @ 12fr.	48·00
Labour	45·00
Repairs, etc.	20·00
Loss of magnesia (?)	5·00
	118·00

The cost price will not be the same in England, for the simple reason that coal costs there only 6fr. per ton instead of 12fr. as at Salindres. The cost price in England would therefore be—

	Francs.
Coal, 4000kilos, @ 6fr.	24·00
Labour	45·00
Repairs, etc.	20·00
Loss of magnesia (?)	5·00
	94·00

That is to say, in England one ton of Cl will cost the same amount as by the old Weldon process.

To this conclusion two objections may be made:—

1. The cost price of 118fr. at Salindres mentioned above, is a *calculated* cost *not yet realised*. The experience gained of the new process warrants M. Pechiney in expecting that he will realise this result when an experimental plant producing only ¾ ton per day is replaced by an installation working on a scale of 6 tons per day, and to the working of which an experience which increases every day will be applied. It is with the expectation that the above estimate will be the maximum rather than the minimum that this probable cost price of 118fr. is given.

2. Wages, it may be said, are much lower in France than in England. Consequently, if 45fr. is the cost for labour in France a much higher sum will be required for England. An English workman, however, does more in a day than a French workman. So that, notwithstanding the lower wages in France, the expense for labour *per ton of material produced* is nearly the same in both countries.

The cost in England of 1 ton of chlorine obtained from the old Weldon process as compared with the Weldon-Pechiney will be as follows:—

1.—THE OLD WELDON PROCESS.

	£	s.	d.
Cost price of 1 ton of chlorine 94fr. =	3	15	0
Value of 3⅓ tons of HCl gas at 56s. =	9	6	0
	13	1	0

2.—WELDON-PECHINEY PROCESS.

	£	s.	d.
Cost price of 1 ton Cl 94fr. =	3	15	0
Value of 1⅓ tons HCl gas at 56s. =	3	14	0
	7	9	0

Therefore the saving by the latter process = £13 1s. less £7 9s., or £5 12s. per ton of Cl produced.

But, alas! where will the English manufacturer sell his bleaching powder if he produces 3⅓ tons instead of 1⅓ tons, as now?

But there are other matters to be regarded in considering the applicability of this process. In 1884 Mr. Weldon expected that its first effect would be to replace the Leblanc process by the ammonia process: because he then thought it probable that his new chlorine process might be used in conjunction with a method for decomposing the residual NH_4Cl of the ammonia soda process by MgO. And, although it is not my intention to go into that part of the question now, there is no doubt that that end could be attained if ammonia soda makers were willing to add to their already costly plant the additional expensive plant which would be necessary. M. Pechiney has patented a process and apparatus for thus treating NH_4Cl; and, moreover, Mr. Chance has proved that it is easy to transform calcium chloride into magnesium chloride by treating it with carbonic acid in presence of magnesia.

And this leads us to the more serious question, as to whether English manufacturers will care to use this new chlorine process in conjunction with the Leblanc soda process. In considering this question, we have to face the difficulty that magnesium chloride exists as a raw product at a place not far removed from a port easily available for the distribution of material, and from which centre enormous quantities of chemical products are already sent out—namely, Stassfurt. In the very able paper on the "Stassfurt Salts Industry," which Mr. Hake read before this Section in 1883 (p. 150), he said, speaking of the residual solution of magnesium chloride: "Many proposals have been made and numerous patents taken out for the further utilisation of this mother-liquor, but it still figures largely as a waste product. Of the 6,000,000 cubic feet yearly produced, corresponding to 150,000 tons of dry $MgCl_2$, one-half only is recovered, the remainder being run into the river, carrying with it 300,000lb. of bromine." Chloride of magnesium therefore costs at Stassfurt practically nothing. It is run into the rivers in the form of a solution almost as concentrated as that which is made at Salindres by dissolving the MgO of the process in HCl. The solution, therefore, has to undergo no more evaporation than is now made at Salindres, the cost of which is included in the estimated cost price of 118fr. per ton of Cl. However, as the Stassfurt solution contains some foreign salts (especially SO_3MgO and NaCl), which are deposited during the concentration, one may admit that the operation costs a little more than the evaporation made at Salindres, say 2·50fr. more per ton of $MgCl_26H_2O$—or for 3¾ tons, corresponding to 1⅓ tons Cl, 9·37fr., say 10fr. more.

	Francs.
The cost of 1 ton Cl at Salindres being	118·00
Will be increased, as we have shown, by	10·00
And will thus become	128·00
But it is still necessary to deduct for the loss of magnesia (which will be nil at Stassfurt, where $MgCl_26H_2O$ has no value), say	5·00
The cost of Cl per ton at Stassfurt will thus be	123·00

Or say £5.

To arrive at this result, it is assumed that fuel and labour cost the same at Stassfurt as at Salindres. In which case, chlorine and chlorine products will be produced at a much cheaper rate at Stassfurt than in England. On the other hand, Stassfurt is not so well situated as the English works for the exportation of B. P. However, the difference in this respect will not be great. The carriage from Stassfurt to Hamburg is about 6s. per ton by water and 9s. by rail. And the situation of Hamburg is as good on the whole for exportation as that of the English alkali works.

It would seem clear, therefore, that the natural place for the adoption of this process is Stassfurt. And if it can be worked there as economically as I expect it will—producing chlorine at less than one-half its present cost, it will become a serious question whether, even with the advantages which Mr. Chance is securing for it, the Leblanc process will be able to stand against its competitor. If this process succeeds at Stassfurt, the natural result in England will be a decrease of the amount of soda made by the Leblanc process, and an increase of the happiness of the ammonia soda makers. Mr. Mond and Mr. Solvay may, and probably will in time, succeed in developing their respective processes for producing chlorine from NH_4Cl and $CaCl_2$; but it will take a great deal to beat this process if it is applicable to the refuse chloride of magnesium of Stassfurt.

I will only say, in conclusion, that I think Messieurs Pechiney and Boulouvard deserve the very highest commendation for the labour, zeal and ingenuity which they have expended on the development of this process. There can be no doubt that the enormous personal enthusiasm which Mr. Weldon had, and the marvellous power he possessed of communicating a share of that enthusiasm to others, has been the mainspring which has induced these gentlemen, as a matter of honour to his memory, to endeavour to finish this work, believing all the time that it would ultimately attain that success which he had anticipated. I cannot conclude without quoting a few words of the inventor of this process, uttered from the spot on which I now stand. In his note on the influence of the ammonia soda process on the value of hydrochloric acid (see this Journ. 1883, 435) Mr. Weldon said: "If this process succeeds, *and I am still among you*, I will ask permission to give an account of it before this Section: and I can imagine few things more delightful than to be able then to tell you that the old Weldon process, after having forced its way into every chlorine works in the world except two, and those unimportant works, peculiarly situated, has at last passed into the limbo of things which have served their time."

NOTE.—I have to acknowledge the very great assistance I have derived from Mr. Renaut, Secretary of the Weldon's Chlorine Processes Company, in the preparation of this paper.

DISCUSSION.

The CHAIRMAN said the paper was one of singular interest from every point of view. Though it raised painful memories of the loss they had sustained by Mr. Weldon's death, everyone must feel a deep satisfaction in the fact that his labours had not been lost, and that his French fellow-workers had been able to carry out his plans with such marvellous skill and perseverance. The President had given a most beautiful exemplification of the fact that the highest science may find its application in technical chemistry, by working out before the meeting the real character of the reaction which took place in the process described. This was a process which proved the importance of engineering skill in its relation to manufacturing chemistry. He was not one of those who shared the delusion that the future of English manufacturers would be greatly helped by technical education given to boys of fourteen. Something was wanted which no boy of fourteen ever had—viz., the highest skill in pure chemistry coupled with a sound knowledge of physics, and to both must be added engineering capacity of the highest order, if any real progress was to be made in manufacturing chemistry. Without such knowledge even skilled chemists were apt to fall into the error of supposing that because an experiment went well in the laboratory it would go equally well when tons were dealt with—forgetting the enormous cost of manipulating large masses of material.

Sir HENRY ROSCOE heartily endorsed the remarks of the Chairman as to the importance of engineering skill to applied chemistry. At first sight he had been almost frightened by the complicated character of the apparatus shown—many parts of which, especially the glass-tube cooler, were striking examples of engineering skill and attention to detail. He would like to know whether bleaching-powder could be made from gases containing at the maximum only about 8 per cent. of chlorine, or whether M. Pechiney had confined himself to the manufacture of chlorate only. No doubt the late Mr. Deacon had made bleach from a very dilute chlorine, but he could not remember whether its strength was ever so low as 8 per cent. The question of technical education was not to be settled by merely teaching boys. Masters needed teaching as well; and the highest scientific instruction was needed in order to bring England up to the mark—or rather to keep her there. This process had been worked out by the skill of two eminent French engineers, but Mr. Weldon's own work was a brilliant example of what Englishmen could do. With such workers, and with higher education, England would not fail to keep her position.

Sir FREDERICK ABEL was glad to have an opportunity of expressing the pleasure he had felt, not only in listening to an interesting account of the last work of his friend Weldon carried on to completion by M. Pechiney, but seeing Professor Dewar throw himself, as they knew he could, with the greatest ease, from the highest branches of physical chemistry into the elucidation of practical processes, to the advantage of those who followed them, and thus illustrating the importance of a thorough education in all branches of science.

Mr. ALEXANDER M. CHANCE thought that the Chairman had called upon him for an opinion three months too soon. He might have something to say about it when he read his paper in March.

Mr. E. K. MUSPRATT was glad to find in the President's opening remarks a confirmation of the opinion he had expressed in addressing the Society from the same position — viz., that progress in industrial chemistry had now taken the form of the development of chemical engineering. The ammonia-soda process, as patented by Dyar and Hemming, in 1837, was perfect chemically, but his father and Mr. Young had failed to work it economically simply because their apparatus was imperfect; and M. Solvay's merit lay in the fact that he had overcome the engineering difficulties. However interesting the process under consideration might be from a chemical point of view, if it was to become a manufacturing process it could only be by reason of the perfection of the apparatus employed. And it would be seen by the diagrams exhibited that it was not a question of one piece of apparatus, but of a whole series. In going through the works of Messrs. Pechiney & Co. he had been deeply impressed by the admirable manner in which every engineering detail had been carried out. M. Pechiney's glass-tube cooler was most ingenious. Mr. Deacon had tried to cool the hot gases coming from his decomposer by a glass-tube apparatus in which the tubes were arranged vertically, instead of horizontally, as in M. Pechiney's apparatus; but his tubes broke so rapidly that he had to abandon the idea. M. Pechiney got his tubes from Belgium, and they were probably better than the English tubes. With respect to the question of the cost of the process and the probability of its going to Stassfurt, he did not think anyone could yet speak positively. It was true that at Stassfurt the raw material was in one sense much cheaper than either in England or France; but then the working loss of magnesia was put at only 5fr. out of 118fr., or, say, 5 per cent. England, on the other hand, had a great advantage in cheaper fuel; for it would be seen that simply on account of the higher price of fuel, the ton of Cl cost 25 per cent. more at Salindres than it would in England. He was not familiar with Stassfurt, but he understood that the fuel in use there was an inferior quality of lignite, and there would be difficulties in obtaining the high temperature required, which would make the fuel dearer. He did not fear, therefore, being absolutely bowled over by the Stassfurt manufacturers. He thought it probable that there would be some, though not insurmountable, difficulty in making bleach from a dilute chlorine such as this process yielded. The average strength of Deacon chlorine was 9 or 10 per cent., and he knew that with that percentage it was difficult to absorb the chlorine in hot weather. For the manufacture of bleaching liquor and chlorates, however, such a dilute chlorine would be quite applicable—it being merely a question of size of apparatus. M. Pechiney at present used the chlorine obtained by the new process for the manufacture of chlorate of potash. If he could produce his chlorine in that form cheaper than could the English manufacturer, the latter would be affected just as much as if bleaching-powder were produced, since the two manufactures were, so to speak, convertible. The effect would be that the English manufacturer would be able to make bleaching-powder only. He did not take a despondent view of the future of the English chemical trade. Though England might have fallen behind in some matters, she had advanced in others. English workmen were still, taking them all round, equal to, if not better than, Continental workmen. What was wanted was a more thorough education of the higher middle-class, and that would, he believed, be supplied by such institutions as the Owens College, and the new colleges at Liverpool and Leeds.

Dr. D. B. Hewitt was not prepared to criticise the process. Such an invention, however, was a matter of the greatest interest to everyone concerned in the manufacture of soda or chlorine products. Many active minds were at present engaged on similar problems, and he expected great advances to be made during the next five years. The result of increased knowledge might appear to be at one time to pinch the ammonia manufacturer, or at another time the Leblanc manufacturer; but, in the end, no one would find himself much the worse, and the human race would be benefited. An increased population and growing civilisation would create an increased demand for these articles in proportion to the development of the processes producing them. It was extremely remarkable that notwithstanding the vast development of the ammonia soda process, the decomposition of salt in England by the Leblanc process had been affected very slightly; and the Leblanc soda manufacture still showed a remarkable vitality. With respect to the utilisation of dilute chlorine, long experience enabled him to express a firm conviction that there was no difficulty whatever in making bleaching powder with chlorine that varied from 4 to 8 per cent. by volume. In a Deacon chamber there was no difficulty in absorbing the Cl to the very last traces. That he had proved to the satisfaction of Dr. Angus Smith. The whole difficulty consisted in obtaining the gases free from any bodies which would spoil the bleach. If the gases contained neither carbonic acid, hydrochloric acid, nor water, good bleach could be made even if only 3 per cent. by volume of chlorine were present in the mixture of gases. Of course as the percentage of chlorine decreased it became more difficult to exclude these deleterious bodies. With respect to the apparatus employed in this process, and especially the glass-tube cooler, words failed him wherewith to express his admiration. The glass-tube cooler seemed to him to have great advantages over the ordinary coke tower for very hot vapour of water mixed with chlorine and hydrochloric acid. As to whether more chlorine would be made at Stassfurt or in England no one could at present speak positively; but there could be no doubt that a great reward was in store for whoever should solve the problem upon which so many scientific men were now at work.

Colonel Gamble had not seen the process in operation. He had seen the plant in course of construction nine months ago, and, like everyone who had seen it since, was struck with the amount of engineering skill expended on it. M. Pechiney's belief then was that this process would be the chlorine process of the future—whether of two years hence or twenty years hence M. Pechiney thought might be questionable, but the speaker feared that most chlorine manufacturers now regarded that future as much nearer than they had hoped. The position was a most serious one for the Leblanc manufacturers of this country. They were already blessed with too much chlorine, in the shape of muriatic acid, and had to restrict its use as much as possible in order to make any profits. If the amount of available chlorine from each ton of salt was to be more than doubled, he did not know what would become of them. He feared Mr. Muspratt had hardly expressed the effect of the possible Stassfurt manufacture as fully as he might have done. He had said that the 5 per cent. loss of magnesia would be balanced in England by cheaper fuel, etc. But the fact was, as Mr. Muspratt was aware, that at Stassfurt they would have not only magnesia but chlorine also for the cost of evaporation. That being so, he feared that bleaching powder would soon be very cheap at Stassfurt, if the process could be satisfactorily carried out with their waste magnesium chloride.

Mr. John Pattinson quite concurred in the views expressed by previous speakers, that there appeared to be considerable danger of the transference of the chlorine industry from England to Stassfurt; and that real progress in industrial chemistry was now more dependent on the application of engineering ability than on the invention of new chemical processes.

Mr. A. E. Fletcher thought that, beautiful and ingenious as the apparatus appeared to be from the diagrams shown, manufacturers would look with dismay at the number of parts, knowing as they did that each part would add to the cost of production and maintenance. If, however, this elaborate apparatus produced results not to be obtained otherwise, then all thanks were due to the engineers who had designed it. The condenser had a special interest for him, and appeared to be extremely ingenious and effective. It should not, however, be compared with a coke tower. The latter was well suited to the conditions of the chlorine manufacture as now carried on, the supply of acid being intermittent, and it being therefore necessary to hold a large store of water in reserve, and available for use at any moment. M. Pechiney's condenser, on the contrary, was intended to deal with a constant supply of acid. It had been said that good bleach could be made from very dilute chlorine if it were pure. But of course dilute chlorine was not pure; and although elaborate arrangements might be devised for excluding noxious elements, there would always be the danger of leakage, and thus of the presence of carbonic acid or vapour.

Mr. Thomas Royle inquired on what scale the drawings were supposed to be.

Dr. Alder Wright asked whether it would not be possible to recover economically some of the HCl lost in drying; secondly, whether the percentage of Cl would not be increased by decreasing the air supply during the process of decomposition, and thus diminishing the total volume of the gases; and, thirdly, whether, supposing the process to be worked at Stassfurt, the by-product of magnesia which would result would not be available for use for making fire-bricks, thus cheapening the production, and perhaps turning the scale in favour of Stassfurt in a way not anticipated.

Mr. C. T. Kingzett remarked that some 16 years ago he had been associated with the late Mr. Weldon in experimenting a process for the production of chlorine by means of magnesia. In that case no attempt was made to utilise the chlorine directly for the manufacture of bleaching-powder. It was converted immediately into bleaching-liquor. Referring to this more modern form of the process, it appeared that the oxychloride as finally treated contained a large percentage of water. The question therefore arose as to how far the chemical reactions had been determined. Was it supposed that the chlorine resulted only from the action of oxygen on the oxychloride, or did it result in part from the action on the vapour of HCl generated in association? If it resulted from the direct action of air, then Leblanc soda makers would surely have an easy method of utilising their spare HCl by means of a little magnesia. The process might possibly be improved by moulding the magnesia into blocks suitably arranged so as to be alternately converted into oxychloride by HCl and then decomposing by heat, with the result of the production of chlorine.

Mr. J. W. Swan thought it would be useful if Professor Dewar could state the relative cost of the apparatus for this process and the old Weldon process; and also to what extent the HCl was actually condensed.

Professor Dewar in reply said: With regard to the question put by Sir Henry Roscoe, that was the point which first struck me and led to my investigation of the nature of the reaction in the furnace. Of course the practical reply to that question is that no user of the process on a large scale would ever allow his yield of chlorine to go below 5 per cent. As to the assumed difficulty of making bleaching powder from such chlorine, I think the testimony we have had to-night from so high an authority on the subject as Dr. Hewitt, confirming as it does what he said before the Newcastle Section in April, 1885 (this Journal, vol. iv. 311), quite settles the question. If Dr. Hewitt could make 36 per cent. bleach from gases containing only 5 per cent. of chlorine *by weight*, there would surely be no difficulty in dealing with these gases in which the chlorine averages 5 per cent. *by volume*. Moreover, Mr. Mond has always scouted the idea that any real difficulty attached to this point. But even if any such difficulty exists now it will disappear when we succeed, as we certainly shall, in increasing the temperature of the furnace and thus obtaining a quicker decomposition and a higher percentage of free chlorine. I have already made to M. Pechiney the suggestion which Dr. Wright has made to night—namely, that the supply of air should be graduated. With respect to the suggestions made by Mr. Kingzett, I would remark that the oxychloride does not need to be made into blocks; it is a natural property of the material to be somewhat too "blocky." In practice it has been found necessary to use it in small pieces, so that air may thoroughly permeate the mass. Mr. Swan's question is a most pertinent one. I have already stated that the plant for this process will be more expensive than is the plant for the old Weldon process. In fact, M. Pechiney estimates that, taking the unit of chlorine production at one ton per day, the cost of plant at Salindres for the old Weldon process would be 60,000fr., and for the new process 120,000fr. —that is to say, exactly double. The diagrams shown to-night are not drawn to scale. They are merely illustrations for the purpose of this paper. I may say, however, that the chambers of the decomposing furnace are three metres high, one metre long, and 0·08 metre wide. The hydrochloric acid at present lost could undoubtedly be recovered if it were worth while to do so: but at Salindres they are in the happy position of having a very extensive area and no alkali inspector, and therefore this loss does not trouble them. With respect to the possibility of Stassfurt becoming a centre of the chlorine industry, I should like to quote a few words of my distinguished predecessor in office. In his able address to this Society in July, 1886, Mr. Muspratt said: "If chloride of magnesium is used to replace salt as the raw material for chlorine, this great chemical industry will, of necessity, have its seat in Stassfurt, and not in Lancashire." I think, therefore, that my views on that point are well supported. I of course admit that the process has its difficulties, but I believe that those difficulties will be overcome. For instance, the attainment of a higher temperature in the decomposing furnace will obviate the present loss of chlorine as hydrochloric acid. The oxychloride before desiccation contains 6 equivalents of water; after desiccation it contains only 3 equivalents. If the drying were stopped earlier scarcely any hydrochloric acid would come off in that operation; but we cannot do that until M. Pechiney has carried out his improvement in heating the furnace. Then with respect to the remaining difficulty of undecomposed oxychloride. That will be no great drawback where the process is worked continuously, because these small portions of oxychloride are easily separated from the residues and are worked again. Supposing the process in work at Stassfurt, there will be an accumulation of cheap magnesia which will have been heated strongly, and will therefore be very dense. This magnesia will contain some 2 or 3 per cent. of chlorine, and will therefore be in a condition to form an excellent cement, setting quickly and with a hard, white surface. As Dr. Wright has suggested, such a cement will probably find useful applications, and may thus constitute a source of profit.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held 5th December, 1887, in the Chemical Theatre, University College.

DR. J. CAMPBELL BROWN PRESIDING.

MISCELLANEOUS COMMUNICATIONS.

Dr. J. Campbell Brown said that he had brought some specimens of native indigo plant from Matacong, off the coast of Africa, and some indigo products, whilst a gentleman had been good enough to send a specimen of wild African indigo. The African indigo plant was extremely rich in indigo, and it was extensively used by the natives. They brought it down to the coast in the form exhibited (which was a number of conical masses of leaves) for their own use. It was very rough, and as far as he could make out it was matted together by cow-dung, and they used that for dyeing their own goods. The process they followed was similar in its essentials to that employed in India and elsewhere. They extracted it with alkali in such a way that fermentation took place; this developed the indigo, reduced it and dissolved the white indigo, and as far as he understood the natives on the African coast gave the goods rather a prolonged dipping. It was interesting to know, also, that although the specimen submitted contained a great deal of indigo it was difficult to get all the indigo blue from it. Dr. Kohn has worked this out, and found that the difficulty arose from the fact that the indigo was partly converted into indigo-brown, and that led him (Dr. Brown) to endeavour to ascertain how it got into that condition, and then he found out that the leaves were mixed with something like cow-dung. It had been put up in that form apparently for convenience of carriage. In that way it had got during carriage a strong fermentation and heating set up by the presence of the cow-dung and by the climate. In cases of what might be called "over-fermentation," not only was indigo blue formed from indican, but the continued fermentation made indigo brown. There were on the table specimens of indigo brown, indigo blue from indigo plants, and some artificial indigo made from coal-tar. It was also interesting to note that in different parts of the world where the climate is similar, indigo plants grow and flourish.

Mr. W. P. Thompson exhibited some samples of prepared paper for bank cheques. The cheques are printed in black or any other colour, but the paper was impregnated with chemicals in such a manner that no matter what liquid was put on to try to take out ordinary writing ink, the paper would change colour with the liquid, though unaffected by water. The samples he had got, if washed with caustic soda solution, oxalic acid or other acid, or bleaching powder solution, would entirely change colour, showing clearly the tampering. This prepared paper was being largely used in France in making cheques, coupons, bonds, etc. Envelopes have also been made with this paper, so that tampering with them could easily be detected.

The Chairman: Is the colour printed on the cheques?

Mr. W. P. Thompson: No, it is in the white paper itself. It is printed with ordinary printer's ink. If oxalic acid were put to the paper, it would immediately change colour, as shown in some of the specimens exhibited smeared with the three aforesaid solutions.

◆◆◆

ULTRAMARINE.

BY HERBERT J. L. RAWLINS.

Lapis-lazuli, the native form of ultramarine, is a somewhat rare mineral found in Prussia, China, Persia, and one or two other localities. It is generally of an earthy bluish-grey colour, but the purest varieties are of a deep rich blue. It is associated with iron pyrites, generally in small glittering crystals, and this gave rise, at one time, to the idea that the blue colour was due to the presence of iron.

To procure the blue colour free from the earthy matter accompanying it, the mineral is first reduced to a fine powder, which is mixed with resin, wax, and linseed oil, worked into a paste. The mass is then placed in a cloth and kneaded under water. The first portion of the colouring matter expressed is generally dirty; but afterwards the brighter blue makes its way through the cloth, and last of all an inferior quality. All these qualities are carefully collected and classified.

This operation is a very tedious one, and though several others have been suggested, no better one has been found. The resulting blue pigment is certainly of great stability and purity of tone, but costs about 20s. per ounce.

Discovery of a Process of Manufacture.

For a long time the composition of this body remained a mystery. "What is lapis?" asks Sir Hugh Evans in the "Merry Wives of Windsor," and until half-a-century ago chemists were echoing his question and asking each other "What is lapis-lazuli?" The analysis could give no clue as to the cause of the blue colour. To prepare it artificially became a great object, and the efforts in this direction were stimulated by the offer of prizes, amongst which was one of 6000 francs, offered by the "Société d'Encouragement" of France, to be awarded to the discoverer of a method of making ultramarine, provided it did not cost more than 90s. per lb. How strange it seems to think of this in these days when the value has fallen to less than half that price per cwt.!

As early as 1814 two German chemists, Tessärt and Kuhlmann, had observed the formation of a blue product in soda kilns and calcination kilns, but Guimet, in 1828, first discovered how it was produced, and gained the 6000 francs prize. He did not, however, publish his method, and grew immensely rich, although the price sank to about 16s. per lb. In 1828 he was producing at the rate of 120,000lb. annually.

About the same time, or, as is positively asserted by some, even prior to Guimet, Gmelin made the same discovery and published his researches in full, thus perhaps laying the foundation stone of the present supremacy of Germany in this manufacture.

Chemical Constitution.

In spite of the valuable discoveries of Hoffmann, Unger and others, our knowledge of the chemical constitution of ultramarine is very limited and uncertain, many different theories having been advanced regarding the cause of the blue colour.

According to Wilkins, ultramarine is composed of two portions, one of which consists of two silicates of alumina with sulphite and sulphide of sodium, and is constant in its composition; the other being a mixture of variable quantities of sand, clay and oxide of iron, with sulphuric acid. The blue colouring principle he considers to be a compound of sodium sulphite and sulphide. Another ingenious theorist, Stein, in two papers published in the *Jahresberichte* in 1871 and 1872, concludes that blue ultramarine contains sulphurous, and not thio-sulphuric acid, that neither sulphites nor thio-sulphates are necessary to its composition, and that it owes its colour to the presence of black sulphide of sodium, which is formed at high temperatures by the action of sulphide of sodium on alumina—admitting, therefore, that it is not a chemical compound, but merely a mechanical mixture, the blue colour of which is due to the bodies composing it.

Brunner considers ultramarine to be a compound of aluminium silicate, with sodium sulphate and sulphide, while Brünlin regards it as a double silicate of aluminium and sodium, in combination with pentasulphide of sodium. Green ultramarine he considers to be the same double silicate in combination with bisulphide of sodium.

Again, according to Ritter, ultramarine contains a double silicate, not only associated with polysulphide, but also with thiosulphate of soda: and Schülzenberger, on the other hand, considers that it is a mixture of a double silicate with sulphite and monosulphide of sodium.

Endemann considers that the blue colour is due to a "colour nucleus," consisting of unchanging proportions of aluminium, sodium, oxygen and sulphur, in each variety of ultramarine the proportion being different, while the rest of the sodium and aluminium, and the whole of the silica, merely act as a vehicle necessary to the preparation and existence of the colour. He considers that this "colour nucleus," in the case of white ultramarine, which he calls the "mother-substance in the manufacture of blue ultramarine," has the formula $AlNa_4O_2S_2$. By the action on two molecules of this of sulphurous acid gas Na_2O is removed, and green ultramarine $Al_2Na_6O_3S_4$ is formed, which then, by the action of oxygen, which forms sodium sulphate, passes into the pure green compound, having the formula $Al_2Na_4O_3S_3$. In the "indirect process" of manufacture green ultramarine is converted into blue by being burnt with sulphur. By this means Endemann considers that more sodium and sulphur are removed, and blue ultramarine $Al_2Na_2O_3S_3$ is formed. He considers that the other portion, not included in the "colour nucleus," differs in different samples. In one which he mentions it has about the composition $3Al_2O_3.5Na_2O.16SiO_2$.

But of all chemists who have worked on this subject none has done more to increase our knowledge of "the blue marvel of inorganic chemistry," as he himself has called it, than Reinhold Hoffmann. His position of manager of the Marienberg Ultramarine Works, near Benscheim, in the Grand Duchy of Hesse, renders his acquaintance with the manufacture perfect, and his untiring researches on the subject have been well rewarded by results both interesting and valuable. He considers ultramarine to be a double silicate of sodium and aluminium, together with bisulphide of sodium, the variety poor in silica, characterised by its paleness and purity of tint, and easy decomposition by acids, having the formula $4(Al_2Na_2Si_2O_8)+Na_2S_4$; while that rich in silica, characterised by its dark and somewhat reddish tint, and more difficult decomposition by acids, has the formula $2(Al_2Na_2Si_3O_{10})+Na_2S_4$. He also considers it very doubtful whether green ultramarine is really a chemical compound, and indeed it is now generally considered that the colour is only due to small traces of sodium salts in very intimate mechanical mixture with the blue variety, for by heating the green body for some time at 160° with water, in closed tubes, it is converted into the blue product, and small traces of sodium compounds are found in solution in the water; and further, on heating blue ultramarine strongly with sodium sulphate and charcoal—that is, acting upon it with sodium sulphide—the green variety is formed.

In a paper by Knapp, an abstract of which appeared in the *Journal of the Chemical Society* for March, 1880, there are some curious facts recorded with regard to the colouring agent. It was noticed that when silicic acid was replaced by boracic acid, a blue, nearly as stable in its properties as that of ordinary ultramarine, was produced. It was found that a blue could be obtained without alumina being introduced. Hence silica without alumina, and alumina without silica, can be employed with a certain amount of success. The blue, however, formed without silica, is not so strong or stable as that formed with it.

One very curious property which ultramarine possesses is its power of giving up its sodium in exchange for other metals. Thus, by heating blue ultramarine with a concentrated solution of silver nitrate in sealed tubes to 120° for fifteen hours, a dark yellow *silver* ultramarine is produced, containing about 46·5 per cent. of silver. This corresponds to about 15·5 per cent. of sodium, which is just about the amount that the original body contained.

When this body is heated with an aqueous solution of sodium chloride to 120° in sealed tubes, about three-quarters of the silver is replaced by sodium, but the other quarter cannot be so replaced; in fact, blue ultramarine, when heated with silver chloride, takes up silver, and becomes green. But by heating silver ultramarine with sodium chloride in the dry way, at rather a higher temperature, the whole of the silver is replaced by sodium, but the ultramarine thus regenerated does not equal the original body in colour. The change is probably due to the loss of sulphur in the formation of the silver ultramarine.

If in the above experiment potassium chloride be substituted for the sodium salt, and the temperature not allowed to exceed 400°, a bluish-green *potassium* ultramarine is formed. *Barium* ultramarine is a yellowish-brown product, *zinc* ultramarine is violet, and *magnesium* ultramarine is grey. These may all be obtained by acting on the yellow silver ultramarine with the corresponding metallic chloride.

From the experiments of Dollfus and Goppelsröder some very striking differences have been brought to light between the three types of colour which they examined—namely, the blue, green and violet—in their behaviour with various reagents. Thus, an aqueous solution of caustic soda or potash does not act on the blue or green, but turns the violet to blue, and when heated with carbonic oxide the same result ensues. Many other reagents have the same effect on the violet variety, but when acted upon with sodium sulphide, the green turns grey, and when heated with potassium chlorate becomes darker and loses its brightness of colour. Dollfus and Goppelsröder attempt no explanation of these facts, but simply state them as results of their observations, and profess their inability to give any chemical formulæ for the three ultramarines, though they consider that there is sufficient proof that each has its distinct constitution. They give as their opinion, however, that they are double silicates of aluminium and sodium, in which a part of the oxygen is replaced by sulphur.

I may here mention that violet and red ultramarines are more bodies of scientific interest than of any practical use, as their colouring power is not sufficiently great. The violet variety may be prepared by exposing the underground blue product to chlorine gas under a high temperature, while the red may be obtained from the violet by acting on it, under a low temperature, by dilute nitric acid fumes.

INDIRECT PROCESS OF MANUFACTURE.

The first artificial method of producing ultramarine was that known as the "Indirect Process"—that is, first the manufacture of green ultramarine; and, secondly, its conversion into blue. It was carried out as follows:—

An intimate mixture of Glauber's salts, China clay, and coal or resin, finely ground together, was placed in crucibles and baked or burned in an oven for about six hours. It was then transferred to iron trays, and heated with flowers of sulphur to the point where the sulphur took fire, when it was allowed to burn itself out. By this second process the green was converted into blue. It was then washed, ground with water, and settled out, the first deposit being of a darker shade than the second, and the colour becoming lighter as the powder settled was finer in grind. This is essentially the method employed now at many German works, those at Marienberg, for instance, and produces what is known as "sulphate ultramarine," distinguished by its pale shade and almost *greenish* blue tint.

The Manufacture as Carried out in Muffle Furnaces.

There are, however, some objections to the indirect process, and it was considered advisable to find a plan by which ultramarine could be made in bulk in a muffle furnace. The following is a method which is employed at the present time in some of the German works:—

A mixture of China clay, carbonate of soda, sulphate of soda, sulphur, sand and charcoal or resin, finely ground together, are placed upon the floor of a muffle furnace, being pressed down so as to present an even surface. The mixture is then entirely enclosed with fire-clay tiles, the spaces between which are filled in with thin mortar. When the oven is so charged the front is built up, a small hole being left for watching the temperature of the flue between the tiles and the top of the furnace, and for drawing samples during the process, which is done through a corresponding hole in the front of the fire-clay tiles, temporarily closed with a fire-clay stopper. The oven is now heated—slowly at first, and afterwards more strongly, so that at the end of eight or nine hours it is at a dull red heat. It is kept at this temperature for about 24 hours, when the heat is raised so that a clear red glow is obtained, which is kept up to the end of the operation.

For the purpose of taking a sample, an iron spoon borer is introduced through the hole left in the enclosing tiles, turned round, and pulled out. The contents are laid on a clean tile, and quickly covered with another tile, on which a second quantity is placed, and allowed to remain exposed to the air. If the oven has been sufficiently heated the covered sample should appear of a bluish green, and no longer brown or yellow, while the second sample should be rather bluer. If this be the case, the oven is heated slowly for another hour, and then all communication with the outer air cut off. It is allowed to cool and then opened, when the contents should appear as a beautiful blue mass, the lower portion of which, however, is of a greenish tinge. Both parts are now treated alike, but worked up separately, the greenish blue portion making an inferior article. The finishing process is as follows:—

The raw ultramarine is ground in upright mills, and then repeatedly boiled for about ten or fifteen minutes at a time in cast-iron boilers, being all the time agitated by a mechanical stirring arrangement. It is then allowed to settle, and the water drawn off with a siphon. As soon as the powder settles into a hard compact mass it has been sufficiently washed, and it is then dug out. The part next to the bottom of the boiler is generally coarse and of poor quality. It is carefully separated from the upper portion, which is transferred to wet mills of the ordinary description, and there ground for from six to twelve hours, during which time about 150lb. can be treated in each mill. The ground colour from these mills is then collected in a large tub, and allowed to settle for four hours, during which time the coarsest particles fall to the bottom. The liquid is then passed through a series of tubs, in each of which it is allowed to stand for a period of time, lengthening as the quality settled out becomes finer, the last settling requiring about three weeks. The various qualities are then dried and sifted, when they are ready for the market.

The blue produced by this operation is of a good quality, but there are some objections to the process which have given rise to another in which the ultramarine is produced direct in crucibles similar to those used in the indirect process.

Direct Process in Crucibles.

This is conducted as follows:—The mixture of raw materials consists of about 100 parts of China clay, 90 of carbonate of soda, 110 of sulphur, 20 of charcoal, and a quantity of infusorial earth, varying according as the ultramarine produced is desired to be rich or poor in silica. These are finely ground together, in which process great care must be observed, as much depends upon its being properly carried out. The mixture is then filled loosely into crucibles provided with flat circular lids, which are fixed on with mortar containing clay. This is allowed to dry, and the crucibles are then ready for firing, which process is conducted in ovens generally constructed so as to contain several hundred crucibles, which are arranged in rows, one above another.

The mixture undergoes a very curious change of colour while in the ovens. When put in it is greyish white, and during the process of burning it becomes successively brown, green, blue, violet, red and white in the order named. These changes are, according to Guimet, due to oxidation. The brown appears with the blue flames due to the combustion of the sulphur, the green just after the sulphur flames have ceased, and the blue is first formed at a temperature of about 700°—*i.e.*, a bright red heat. If, after this, heat be still applied and air freely admitted, the mixture becomes first violet, then red or rose coloured, and finally white. When this white body is heated to redness with carbon or other reducing agents, the red, violet, blue, green and brown colours (according to the amount of reducing agent employed) may sometimes be reproduced, though the reaction is by no means a certain one.

If brown ultramarine be removed from the oven, and allowed to remain exposed to the air, it immediately takes fire and burns to an inferior blue colour. The same thing occurs with the green body. Even if the brown product be completely cooled before being exposed to the air, it will, as soon as the air is allowed to reach it, get hotter and hotter, until it is glowing, when it will burst into flame and become blue. Attempts have been made to preserve the brown colour, which is of a beautiful chocolate tint, but have always failed. In one instance, when this was tried, the colour was put immediately into water, and treated like the ordinary blue variety, and as long as it was kept moist no change was apparent. After being washed and wet ground the moist powder was put into a cask, where for some time it was allowed to remain undisturbed. At the end of about three weeks it was noticed that the mass was hot, and on being turned out of the cask and broken up it was found to be at a glowing heat in the interior.

After the oven has been fired for several hours it is carefully closed at every point where air might enter, and allowed to cool for four or five days. The exact length of time during which the ovens are fired, and the amount of air admitted, depend upon various circumstances, one important one being the state of the weather. Thus, on a dull, foggy day, when the draught in the chimney is not good, a longer time is required. Of course, no rule can be given for this, and it is the experience required in the management of the oven that makes the manufacture so difficult to carry out successfully, the early efforts of a manufacturer not unfrequently resulting in the loss of a whole ovenful of raw material. As soon as the oven has cooled the crucibles are taken out, and the contents of each turned out in a solid mass, which must be carefully cleaned with a knife of any badly burned portions, and afterwards broken up and thrown into a cask along with the contents of other crucibles.

This forms what is known as crude raw ultramarine. It contains about 15 per cent. of sulphate of soda, which must be removed before the colour is fit for sale.

For this purpose it is washed with hot water in large tubs, after which it is ground in wet mills to an impalpable powder, and allowed to stand for about an hour in a large tub, in order to remove the coarsest particles and dirt which are sure to be present. It is then removed to another tub, where it settles for four or five hours, and from this it passes to others, where it stands for various lengths of time, increasing, of course, as the powder to be settled becomes finer, the last settling occupying three or four weeks, and producing the strongest quality that can be obtained—that is to say, it will bear mixing with more of a reducing medium, such as mineral white, than would a former settling, for the mixture in each case to be of the same depth of colour.

The water, after the final settling, still continues about five per cent. of ultramarine. This would take five or six months to settle, and as this time could not generally be given to it, it is precipitated with lime water, which has a sort of coagulating influence upon the particles, which can then be removed by filtration. It is a curious thing that this last quality is quite different to the one preceding it, being very inferior in both colour and strength.

After settling, all the various qualities are dried on kilns, and sifted through fine brass wire sieves by means of a fan, which breaks up the lumps and forces the particles through the meshes of the sieve, which must be very close—about 100 to the inch—in order that the ultramarine may be perfectly smooth and free from lumps or grit of any sort. When finished, it should be in the form of an impalpable powder—the finer qualities so fine, indeed, as to feel almost *buttery* when rubbed between the fingers. After this process the different qualities and shades are mixed to certain standards, and are then ready for sale.

The uses of ultramarine in the arts and manufactures are very numerous and important. The most important, from the point of view of quantity, is the manufacture of "square blue" for washing purposes. In the preparation of this article the ultramarine is generally mixed with bicarbonate of soda and some glutinous material, to help it to retain its shape, and is then pressed into the well-known form of small square or oblong blocks.

It is also used largely in the manufacture of blue paint and printing ink and in the preparation of blue mottled soap. The way in which it is employed in the last-named manufacture is worthy of remark. It is added to the soap while it is in a molten state and just before it is allowed to cool, and thoroughly mixed with it, so that the whole mass is of a pale blue tint. If a small quantity of this be removed from the boiler and cooled quickly, it remains of a uniform tint, but in the case of the whole boiler full, where the cooling is very slow, the action is entirely different. Just at the point of cooling, when the soap is going to set hard, the ultramarine—to use a technical expression—"strikes" and goes into the form which gives to blue mottled soap its well-known appearance.

In the manufacture of paper ultramarine also plays an important part. It is here used not only for producing blue shades, but also as a bleaching agent, to counteract the yellow, when white paper is made.

Another important use is in the calico manufacture, where it is used both in the printing of blue patterns and in the finishing of goods. In the case of calico printing, it is mixed with albumen and printed on to the calico, which is then subjected to the action of steam, the albumen being by this means coagulated and each grain of ultramarine surrounded by an insoluble envelope, so that it cannot be washed out of the calico.

The growth in the manufacture of ultramarine has been very remarkable, especially when it is considered how little the process is understood chemically, and what care and patience—to say nothing of the equally important item of capital—are required in the starting of a manufactory. Commencing less than 50 years ago in the works of Guimet, at Lyons, who produced 120,000lb. annually, there are at the present day nearly 40 manufactories at work in various parts of the world—chiefly in Germany—producing about 20 million lbs. per year. The following figures will give some idea of ten years' growth of this industry—from 1862 to 1872:—

	1862.	1872.
No. of manufactories	24	32
Men employed	964	1929
Tons manufactured	3556	8585

From the above numbers it will be seen that in these ten years the manufacture more than doubled itself, the fact being due, however, not so much to the increase in the number of works, which was only one-third, as to the enlarged capabilities of those existing in 1862. Thus, in the works of Dr. Leverkus, near Cologne—the first works ever started in Germany—the number of men employed had, during these ten years, more than doubled, while the output had trebled, and in the case of the Marienberg Works the difference was even more striking, the number of hands employed and the quantity turned out per annum having nearly quadrupled.

Such is a short sketch—from both a chemical and a practical point of view—of this much used, but little understood, body. I have not attempted to go very deep into its chemistry. It was not within the intention of this paper to do so, and besides, to tell the truth, I was rather afraid to plunge into such a troubled sea of contradictory theories. "Patience," says the French author, in, surely, the most extraordinary mixture of metaphors ever put together—"Patience is the crutch by the light of which we follow the road to knowledge without losing the thread of it." Well, it is to be hoped that this will soon come true in the case of the researches on the question of the composition of ultramarine, for if patience has ever been expended upon any subject, it is upon this. Gmelin, Scheurer-Kestner, Stein, Hoffmann, Scheffer—these and many other names make up the brilliant list of those who have endeavoured to wrest this secret from Nature, and yet to-day we are obliged to echo the words written by Hoffmann ten years ago, and to say, "The time has not yet come when a well-grounded theory can be formed with regard to the chemical constitution of ultramarine, or to its physical properties with regard to light—that is, its various colours."

DISCUSSION.

Dr. S. **Hamburger** said that some years ago a discussion took place in a German technical paper as to whether ammonia soda was applicable to the manufacture of ultramarine. Some manufacturers contended that it was, whereas others found ammonia soda not suitable at all. He should like to hear the lecturer's opinion on that point. Again, he had always understood that it was Vauquelin who first noticed ultramarine on bricks in black ash furnaces, and that it was Dumas who gave an explanation of its formation. Dumas added that there was not the least doubt that one day ultramarine would be made from silica, alumina and sulphide of sodium. This suggestion led Engelhart, who translated Dumas' works into German, to commence experiments in that direction, but he died before they were completed. His assistant Leykauf continued his work, and is entitled to the credit of having taught the world how to make ultramarine on a manufacturing scale. Gmelin's experiments did not go beyond the laboratory scale, while Guimet kept his process secret.

Mr. Thompson asked whether the blue colour in kyanite was due to ultramarine and also whether the colour of the sapphire (which generally had a little silica in its composition and was mainly alumina) was likely to be caused by ultramarine? He fancied himself, with regard to the sapphire, that it was more likely to be caused by cobalt, because traces of cobalt had been found in the sapphire mines in the Southern States, but it had struck him that possibly, as there was silica nearly always present, it might be the silica combined with alkali and sulphur that had done the thing, especially, moreover, as the sapphire was always found there in extinct volcanoes, or in volcanic eruptive rocks. Therefore, there was plenty of sulphur for the purpose of forming ultramarine. The blue corundum or sapphire was found in some mines almost to the exclusion of any other colour, but not sufficiently clear to be gems (he had found one sapphire himself which weighed about 10lb., but too opaque and flawed to be of value as a gem), but in other corundum mines there was not the slightest trace of blue, it was all yellow, red brown, white, and grey. In one—Buck's Creek—mine, where it was all grey, except a little blue in one place, kyanite came up in great quantity and it was all blue, or blue and white, just the same colour as ultramarine.

Dr. J. C. Brown said in connection with Mr. Thompson's question, he would also like to ask whether ultramarine was ever transparent.

Mr. Thompson said with regard to the sapphire he believed the colouring matter might be opaque. If they took sapphires and carefully examined them, they would find that the colour is hardly ever uniformly spread over the stone. He had found sapphires which had the colours red, blue, yellow and white all in the one stone, and the blue, when it is found in a stone, is usually in streaks. Well, if they took a very little ultramarine and stirred it up in water, that water would be transparent and blue and to all appearances uniform, much more uniform than the sapphire. In the same way the blue crystal of corundum might be uniformly blue to all appearance and yet be coloured by ultramarine or other opaque colour. To begin with, cobalt blue was opaque and there was very little doubt that sapphire was coloured by cobalt blue or ultramarine, because the colour was so staple.

Mr. S. G. Rawson asked whether the lecturer had ever noticed the formation of crystals of ultramarine, which, he understood, had been prepared in single-refracting crystals belonging to the regular system. As regards the grinding of the ultramarine, did prolonged grinding much alter the colour, because in the case of vermillion the longer the grinding was continued the brighter was the colour.

Dr. Hamburger said he did not mean to say that ammonia soda did not produce ultramarine, but his point was rather whether it was equally suitable and whether the finished product was of the same or an inferior quality. As far as he could remember, the discussion in the German technical papers did not result in anything definite, and the question was left open, whether ammonia soda could replace Leblanc soda as a raw material for the manufacture of ultramarine.

Mr. S. Muspratt said with regard to the ammonia soda, if Reckitt's blue was an ultramarine, he knew for a fact that ammonia soda was used in it.

Mr. Bateson said he had always understood that the objection to the ammonia soda was that it was more voluminous than the Leblanc soda, and therefore the pots could not receive the same weight of charge, and owing to the greater porosity the heat penetrates less easily to the centre of the mass.

Mr. Rawson did not think the lecturer had quite understood his question on the fineness of the grinding. He did not refer to the quality of the ground raw materials as depending on the fineness of their grinding together, but whether the finished product depended on it. He understood that imperfect grinding was quite fatal to the production of the colour.

Mr. Rawlins, replying to Dr. Hamburger, said that, with regard to the use of ammonia soda, it had frequently been used in the manufacture of ultramarine, and was constantly used, he understood, but he himself had not much experience of it. As far as he could make out, it certainly produced ultramarine, but of a darker shade than that made with Leblanc soda. Mr. Rawlins, continuing, said it could not be supposed, in works where the Leblanc soda was used, that ammonia soda could conveniently be substituted, for of course a works when established had to adhere to its known standards and shades, and it would not do for them to change their raw materials, though the ammonia soda produced a very good ultramarine. As regards the discovery of ultramarine, the first works started anywhere were Guimet's. He (Mr. Rawlins) had with him a little historical list containing the dates at which the various works established before 1866 or a little later had been started. It was drawn out by Hoffmann, who, as he stated before, was the manager of large ultramarine works, and he put down Guimet's, which were started in 1829, first on the list. Dr. Leverkus started in 1834. He (Mr. Rawlins) knew that the discovery of ultramarine had been attributed to different people. He had mentioned Guimet because it had generally been considered, as far as he had heard, that Guimet and Gmelin were the two who discovered it from a manufacturing point of view. With regard to Mr. Thompson's question, he could not tell him about kyanite, but he did not think it was at all likely to be the case with sapphire. He had heard of crystals of ultramarine, but had never seen any, and he knew they were very difficult to prepare and very rare. He had mentioned that the grinding had to be done very thoroughly, because the better it was mixed and the finer it was ground, the better was the ultramarine produced. If it was badly mixed it was quite fatal to getting a good result. Mr. Rawlins said that grinding lightened the colour. Raw ultramarine must be ground before it was practicable to use it at all. For instance, a coarse ultramarine could not be used for printing calico. Therefore it was necessary to grind it both for the sake of the colour and for the sake of the way in which it was applied. It was increased in value by grinding because it made it stronger and finer. Before grinding it was of a dark colour, but after grinding it became lighter and brighter. They would notice the two bottles (specimens submitted) marked respectively "dark shade" and "light shade." These were practically the same ultramarine—*i.e.*, the same original bulk of ultramarine, but these were two of the settlings. The very dark one was an early settling and the light one a long settling that took three weeks.

Mr. J. Macdonald asked which one had the finest particles?

Mr. Rawlins: The pale one.

◆◆◆

NOTE ON A FEW INDIAN DYES AND METHODS OF DYEING BY NATIVES.

BY H. S. ELWORTHY, F.C.S.

In the district in which I am engaged—namely Rohilkund, N.W.P.—there are no extensive dyeing operations carried on, the few places that there are being on the smallest scale, and the dyes they use being of the simplest description.

Cotton goods are almost the only kind dyed, as the Hindoos do not wear woollen clothes, and silk and linen are obtained ready dyed from other districts.

Aniline dyes are fast replacing native dyes on account of their greater ease of application, German and English aniline dyes of all colours being readily obtained in the bazaars, many of them being adulterated by over 50 per cent. of their weight with dextrin or British gum. Although these colours are not as fast generally as their own, still their ready application and comparative cheapness, owing to their intense colorific power, is causing them to replace the others more and more completely.

As is stated at first the dyeing operations are carried on in the most primitive fashion, the shop generally consisting of a small room open in front, with a mud floor and perhaps a small verandah outside. The room itself may range from 8 to 12 feet square, and in this all their work is carried on.

Their dye becks and vats are common earthen vessels unglazed, known as *nauds*—large open pans holding 15 to 20 gallons; *khoondas*—flat dishes holding about 1 to 1½ gallons; and *gharrus*—a kind of earthen pot with a rather narrow mouth. Their furnace consists of two little mud walls, with sometimes a copper or iron pan as a boiler, but usually the earthen vessels are used for this.

Their dyes are dried flowers, fruits, barks, roots, and seeds of trees, with occasionally iron salts, ochres, etc. They use a few different kinds of gum produced locally and also occasionally gum resins as colouring matters or mordants. Their favourite mordants are alum and tree barks. These things are invariably dissolved in water, neither spirits nor acids being used. The cloth, if new, is not bleached in any way, being simply washed thoroughly, generally without soap or alkali, dried or not and placed in the dyeing vessel.

Almost the only chemicals which they use as far as I have been able to ascertain are alum, called *phut kurri*, ferrous sulphate, or *hura kussees*, lime or *chuna*, *puppree* or *sujji mittee* crude carbonate of soda containing from 5 to 30 per cent. of carbonate of soda, with small quantities of sulphate and chloride, castor oil and molasses. *Mooltani milli*, a kind of fullers earth, is also used occasionally.

The dyers here seem to have but a very vague conception of anything but the most elementary colours, attempts rarely being made to obtain different shades, and it is almost impossible to get an exact colour or shade twice over.

I shall not mention the aniline dyes beyond saying that they are simply dissolved in water, the cloth dipped in once or more until the required amount of colour is obtained, sometimes drying between the dips. No mordant is used with them, as far as I know.

I will now give a few of the methods used with their own dyes.

Blue.—This is a colour very largely used here, perhaps more than all the rest combined, and it is in this district invariably done with indigo, no aniline dye being used. The method is as follows:—10oz. of indigo are very finely ground up in a flat dish with crude carbonate of soda, and water the grinding continued until the indigo is in the finest possible state of division, the coarser particles being removed by elutriation and reground again and again. Ten pounds of lime from native limestone or *kunka* (a nodular limestone or calcareous tufa, consisting principally of carbonate of lime with a large proportion of clay, oxide of iron and alumina), and 2¼lb. of crude carbonate of soda are mixed with about 7 or 8lb. of water, well stirred and then strained through grass placed on top of a naud (large open pan); this filtrate, consisting principally of caustic soda, is then mixed with the ground indigo; 2oz. of good, stone lime and 1oz. of molasses (which they say causes it to become ready quickly) are added, and it is then allowed to stand overnight and it is ready in the morning. The cloth is dipped two or three times into this liquor, being allowed to dry between each dip. This is said to yield a fast colour. No copperas is used for the purpose of reducing the indigo, though it is possible that the iron in the kunka (impure limestone), which is largely in the ferrous state, may reduce a portion of it. That it is not entirely reduced is clearly proved by the deep blue of the dye liquor. The men seemed quite unable to explain the *rationale* of the process, and the reason why they used kunka instead of a purer form of limestone. All they knew was that it had been handed down from father to son and other limestone could not be used to replace the kunka.

For Wool.—10oz. of indigo, 1½lb. crude carbonate of soda and 2 to 2½oz. of molasses are mixed with 10 to 12 gallons of water and allowed to remain for 10 or 15 days according to temperature. It is then ready for dyeing without further preparation. No lime is used in this for wool dyeing.

Light Blue.—The cloth is dipped once in indigo liquor and dried. Half-an-ounce of turmeric ground fine is put in enough water to cover the cloth (say 4yds.), the latter being at once put in and left therein for half-an-hour, being occasionally moved about. It is then wrung out and dried without washing. The cloth is now green; 4oz. of *anar* or *naspal* (dried pomegranate fruit, *punica granatum*), are boiled with 2lb. of water till one-fourth is evaporated, and after cooling the clear liquor is decanted, and the cloth dipped in twice, drying between each dip; 2oz. of alum are dissolved in enough water to cover the cloth, the latter quickly dipped in, wrung out and dried.

Black.—Cotton goods are first dyed by passing three or four times through indigo liquor and then dried. The following dye liquor is then made up:—*Harra*, the fruit of a tree *Terminalia chebula*, which is one of the fruits exported from India under the name of *Myrabolans*, 4oz.; anar (pomegranate), 8oz.; and water, 4 or 5lb., are boiled together until one-fourth has evaporated, then allowed to cool and strain through cloth. Copperas, 4oz., is dissolved in the strained liquor, and the cloth dipped in and well rubbed, then well wrung out, dried and again passed through the liquor, dried, washed, and is finished.

Another recipe.—Harra (myrabolans) 4oz., water 2lb., boiled together till about one-fourth has evaporated and allowed to cool. When cold the clear liquor is decanted into another vessel; the cloth is dipped twice in this liquor, drying between each dip. It is then put into a solution of 2oz. of copperas in water and finally wrung out, dried and then washed.

Red.—There are a number of different recipes for red dye, some of them giving a fine fast colour, but many of them are unable to stand washing. Among others the following dyes are used:—*Munjeet* (*East Indian Madder, Rubia Cordifolia Linn.*) *Al* the root of *Morinda Tinctoria* or *M. Eliptica*; Harra (Terminalia Chebula fruit): *Kaifal* or *Kaifala*, a species of red bark which I am unable to trace. Many others are used in different places, but these are about the only ones here.

One recipe is as follows for 4yds. of cloth:—Harra, 8oz. coarsely ground and put into enough water to cover the cloth, which is then well rubbed about in the liquor without further preparation. After half-an-hour to one hour the cloth is well wrung out and dried; 8oz. of alum are dissolved in the same quantity of water, and the cloth quickly wrung through this and dried for three or four days; it is then well washed in the river *Dhobie* fashion—that is, dipped into the water, then raised over the head and brought down on the flat stone with a vigorous swing: 8oz. of *Al* ground up in cold water is allowed to remain in the sun for a day, then just brought to a boil and while still hot the cloth is dipped in, wrung out and hung up in the sunshine to dry. It is again well washed and passed through the *Al* solution once more. A final washing and drying complete the operation.

Khaki-Maju—a fruit, botanical name unknown to me—one fruit for 4yds. of cloth well ground, two anar fruits also well ground are put into enough water to cover the cloth, and 4oz. of Mooltan earth, a kind of fullers earth, added. The cloth is then well rubbed in this liquor for an hour or more, after which it is wrung out. A pinch of copperas is put into enough water to cover the cloth and the latter wrung through quickly; 1oz. of alum is put into the original dye liquor with the maju, etc., and the cloth put in once, wrung out and dried.

Yellow.—There are also a number of ways of dyeing yellow yielding different shades and also of various degrees of fastness. *Thoun*, the seeds of *Cedrela toona (Roxb) Harsinghar*; the flowers of *Nycthanthis Arbor tristis*; *Kusum* or *Safflower Carthamus tinctorius*, *Al*, *Morinda tinctoria*, (also used for dyeing red and green) turmeric, *usare* or *revana* (a kind of gum resin), and many others. For 4yds. of cloth the following are taken:—8oz. of thoun, well washed and the dirt allowed to settle, are boiled in enough water to cover the cloth, and when cold strained through cloth. The goods are dipped in for a few minutes and then wrung out and dried; 2oz. of alum are put into the water containing the thoun, the cloth again dipped in, wrung out and dried. This colour is not fast.

For a fast yellow for 4yds. of cloth:—4oz. of turmeric or harsinghar are put in enough water to cover the cloth, which is then well rubbed in the liquor for about 15 minutes and then wrung out and dried. When dry, it is thoroughly washed in the river until all smell of turmeric is removed: 1lb. of mango bark, bark of *Mangifera Indica*, is well ground up and put into the same quantity of cold water, and the cloth steeped in this for one hour and again wrung out and dried; 4oz. of *anar* and 4oz. of *thoun* are boiled in water and when cold strained through cloth. The goods are put in the clear liquor and after remaining a quarter of an hour wrung out and dried. 1oz. of alum is finally disolved in the water with the anar, etc., the cloth just dipped in, wrung out and dried.

The method of stamping or printing cloth in use here is, as might be expected, extremely simple. The blocks of wood, cut to the desired pattern, are usually small, rarely exceeding 6 or 8 inches in length by 4 or 5 inches in breadth. The colours having been prepared and thickened to the required density, are spread upon a piece of banät or felt, and the block is pressed on this and then applied to the cloth, the operation being repeated as often as necessary. The calico printers here use a kind of gum called dhaura, which is obtained from *Anogeissus Latifolia* (Wallace), and which they consider superior to the Indian gum arabic obtained from *Acacia Arabica Willd*, the babool tree of the native. Dr. Watts, in the "Economic Products of India," says of the dhaura gum: "It is extensively sold for use in calico printing: it occurs in clean, straw-coloured elongated masses, sometimes honey coloured or even brown from impurities. As an adhesive gum, it is inferior in strength to gum arabic, in consequence of which it commands a much lower price in Europe; the more so, since it is nearly always mixed with the bark of the tree, sand, and other impurities, and adulterated with the brown tears, which are probably derived from some other species of *Anogeissus*. In India, the reputation of this gum stands high with the calico printers, especially of Lucknow, and it is probable it possesses some specific peculiarity justifying the preference, since it is used with certain dyestuffs, such as with haldi (*Circuma longa*), while gum arabic or babool is used with madder (*Rubia Cordifolia*). Dhaur or bakli (dhaura) gum is generally collected in April." I can confirm what Dr. Watts says about this gum, and it is probably on account of the tannin which all the samples I have examined contain, as shown by the black colour given with ferric salts, that it is preferred in some cases and not in others.

In my opinion, it would be found a useful gum in the dyeworks of England, yielding a thick viscid liquid much superior to dextrin or British gum, and being at the same time cheaper than gum arabic. I find that when mixed with a small proportion of hydrochloric acid, the liquid gum keeps good for several months even in this climate, and although its adhesive qualities are slightly lessened by this addition, it answers very well for labels, etc. Another gum occasionally used by the printers is the dhak of Dhaka, from *Butea frondosa* (Roxb.), which occurs in small ruby-coloured grains, which dissolve freely in water to a clear red solution, but having very little adhesive power. The colour has been extracted and used as a dye, but not with much success, I believe.

The colours printed here are few in number, and for the most part kutcha, or not fast. I will mention one or two.

Yellow.—Scraps of iron are put into a naud, or large earthen pan, and the pan filled up with water. Say, take 10lb. of iron, 10lb. of water, and ½lb. of molasses, and allow to remain 4 to 15 days, according to the weather. 2½lb. of copperas is boiled in the water that is poured off from the sediment of the iron scraps till 8lb. are left, and when cold, enough dhaura gum is mixed with it to thicken it for printing; it is then added to the deposit from the iron, and the mixture strained through cloth. It is now ready for use. 1¼lb. of sujj (crude carbonate of soda), or 1¼lb. of good stone lime are mixed with about 10lb. of water. After the deposit has settled, the clear liquor is poured off and the cloth is dipped in; it is at once taken out and wrapped up well in a cloth and kept until the colour comes out properly, and then taken out and dried. After washing it is ready. This is said to be a very fast colour.

Black.—For 10yds. of cloth, take ½lb. of hurra broken up fine and mix with enough cold water to wet the cloth; to this add ½lb. of milk. The cloth is put into this liquor without previous straining and well rubbed about for half-an-hour, then well wrung out and allowed to dry in the sun. The cloth is then printed with the iron liquor prepared as for the previous recipe. The ground of the cloth is of a slightly greenish-yellow colour. After drying, it is thoroughly washed and again dried. ½lb. of *Al* (Morinda tincturia) is roughly ground and added to enough water to cover the cloth, and the latter put in and well boiled; it is then allowed to stand all night, and next day wrung out and dried. After washing, the ground is white, while the black colour is very fast.

Green.—½lb. of *naspal* (pomegranate fruit) is boiled with 2½lb. of water till 2lb. remain, and the clear liquor poured off. ½lb. of turmeric is well ground and mixed with this liquor and well strained through cloth. Enough dhaura gum, say about 6oz., is then mixed with the liquid to thicken it. A little indigo is well rubbed up in a *khoonda*—a flat earthen pan—and mixed with the thickened liquor, a piece of cloth being marked with it from time to time until the right shade is obtained.

Red.—Another recipe—for printing. First treat the whole cloth with hurra as in previous recipes. Then 4oz of alum is dissolved in 2lb. of water and a piece of "*Gairu*" stone, a kind of red ochre, rubbed in the vessel until the water reddens, and enough dhaura gum added to thicken it for printing. The cloth is stamped with this, and allowed to dry in the sun for from four to eight days and then washed. ½lb. of "al" is ground up in water and stood in the sun for a day, then just brought to a boil, and while still warm the cloth is wrung through and dried. This operation is repeated once more, the cloth being finally washed and dried. It is a fast colour.

I regret that, owing to the part of the country in which I am situated, I have been unable to obtain any information about the beautiful colours that are used in many parts of India—such as in the Punjaub, Kashmere, etc.—except what has been already published, and which is therefore accessible to the members of this Society.

I have obtained a few specimens of crude dyestuffs, which I forward for the inspection of those interested, and shall be pleased to furnish samples or information on any point as far as possible.

DISCUSSION.

Dr. Brown said that the mode of dyeing black with iron (referred to in the paper) was something like *inking* the cloth. He also noticed that they seemed to use soda in India with the indigo, while in Africa they appear to use potash. He was sure the Society was very much obliged to Mr. Elworthy for bringing the dyestuffs before the meeting and for his interesting paper.

MR. J. J. COLEMAN IN THE CHAIR.

CHEMICAL EDUCATION.

INTRODUCTORY ADDRESS BY J. J. COLEMAN, F.R.S.E., F.I.C., F.C.S.

After referring to the spread of chemical education in recent years, and to the rise of technical colleges, Mr. Coleman said: As members of the Society of Chemical Industry we are chiefly concerned with chemistry as applied to industrial processes, called technical chemistry—technological chemistry or chemical technology, or simply applied chemistry, and which by many is considered a distinct department outside the science of chemistry proper. The line of demarcation between the two has, however, always been hazy, notwithstanding the able way in which Professor Odling has dealt with it in his recent Presidential Address to the Institute of Chemistry. I much prefer to take a different standpoint, and to view the chemist, who concerns himself with research as requiring his education to be in theoretical chemistry, combined with chemical manipulation, and he who concerns himself with chemistry applied to manufacturing operations as requiring his education to be theoretical chemistry combined with chemical engineering.

Now, research chemistry may be in the region of pure science or the region of applied chemistry, and there are a great number of young men who, by physical constitution, or an inquiring mind, are naturally predisposed to remain within the walls of the laboratory, and to confine themselves to manipulative processes, and who shrink from contact with the rough men and the rough processes of a manufacturing business. It is as well, perhaps, that such should be the case; indeed, I have heard of chemical works where the laboratory chemists are not allowed to interfere with the men outside. Even in these cases a little knowledge of chemical engineering must at times be of incalculable benefit to the research chemist, as enabling him to explain intelligently to managers and foremen not only the nature of the processes, but to discuss with them the steps necessary for carrying them out on a large scale.

Some knowledge of chemical engineering is then advisable for a research chemist, and not only advisable, but absolutely essential for a so-called chemical technologist or technical chemist who undertakes the management of men and works—men who, after the type of the late Sir W. Siemens, Walter Weldon, Percy Gilchrist, Sir F. Abel, Sir Lowthian Bell, have shown to this generation what applied chemistry can be made to accomplish. The progress of chemical technology abroad, the flight of some of our chemical industries to German soil, such as that of aniline colours, has been attributed to the skill of the foreign chemists in research, but I would ask, is there not something more than this; has not engineering progressed in Germany *pari passu* with chemistry; and may not success abroad in such matters be attributed as much to good engineering as good research? But just as good civil engineering implies a knowledge of various branches of physics and constructive art, so does chemical engineering require a similar basis. This is fully brought out by the regulation of the new Glasgow and West of Scotland Technical College, which provides that for diplomas in chemical engineering students are to take a three years' course—namely, chemical lectures, natural philosophy, and drawing the first year; chemical laboratory, chemical lectures, applied mechanics and building construction the second year; and chemical technology, drawing, and laboratory practice the third year. Turning to Owens College, Manchester, the course recommended is four years. Probably this is the nearest to the curriculum of the Glasgow College; but, notwithstanding its complexity and length, the course does not include the important subjects to a chemical engineer of applied mechanics and building construction. Drawing is, however, as in the case of the Glasgow College, made very prominent, which indeed is but the carrying out of the weighty words of Sir H. Roscoe, who, in addressing the Manchester Section in 1884, said: "Instruction in mechanical drawing must be of great value to the manufacturing chemist. So strongly do I feel this, that in our instruction in chemical technology in Owens College, this latter subject is made obligatory."

Turning to the calendar of the University College, London, you will find the following words: "It must be remembered that the study, however ample, of pure and applied chemistry, is not sufficient for the successful carrying out of manufacturing operations, even when they are chiefly chemical in character: a fair knowledge of mathematics pure and applied, of physics and mechanics and of mechanical drawing is necessary for all engaged in manufacturing operations. Professor Graham does not, however, lay down any hard and fast line as to what lectures a student should take, or how many years he should work.

I have examined also the calendar of the Yorkshire College, Leeds; of the Firth College, Sheffield; of the Mason College, Birmingham; the University College, Dundee; the College of Science, Durham; and the University College, Bristol: but in none of these calendars is there any mention of applied mechanics and steam, building construction, or freehand, geometrical, or mechanical drawing being necessary for the proper education of the chemical technologist. In most cases they recommend the curriculum of the Institute of Chemistry, which does not include these subjects. I think it would be worth while the authorities of the Institute of Chemistry considering whether there should not be examinations in at least some of these subjects, so as to ensure future fellows being more practical and useful than heretofore in guiding and directing the industries of the country.

In regard to the literature of chemical engineering, it appears to me that little has been done in its systematic treatment. Just as research chemistry wanted a Michael Faraday to write a book on chemical manipulation, or civil engineering wanted a Macquorn Rankin to write a treatise on this subject, so, to my mind, does the chemical technologist want a good treatise on chemical engineering, which will treat of fuel, furnaces, retorts, stills, vacuum pumps, ice and cold air machines, the construction of tanks, roofs, sheds and other chemical plant, with all kinds of rules, tables and data connected with thermodynamics and the science of heat, etc., and the calculations necessary for the multitudinous requirements of the manufacturing chemist.

To my mind the study of the general principles upon which all kinds of plant is constructed is a necessary preliminary to the study of special branches of technology. Some able manufacturing chemists, including Mr. Muspratt and Mr. Ludwig Mond, have expressed an opinion in a discussion at the Liverpool Section of our Society that technology proper cannot be taught properly in colleges. I will not go so far as to endorse this—on the contrary I believe that the highest class of technical education will probably be the working out of special problems under the guidance of the eminent men who occupy our professional chairs, provided the student has had a preliminary and comprehensive education, not only in the principles of chemistry proper, but that of chemical engineering, also.

Passing from these educational questions to the practical matters more immediately concerning our Section, it appears to me that there is considerable room for improvement, both in the number and quality of our communications, and I may add in the attendance at our meetings for their discussion. In this respect we should do well to imitate the activity and enthusiasm of such bodies as the Iron and Steel Institute, the various Gas Institutes, and I may also add of the Civil Engineers, where problems connected with the prosperity of the various industries are vigorously attacked and discussed with right good will, not only by the practical men connected with the works, but by those whose wealth and commercial activity place them at the head of these important industries.

The time is not far back when the very name of manufacturing chemistry suggested secrecy and mystery, and even at this day I am afraid chemists are not exactly of the give-and-take kind of people who get on best in the world. I am one of those who think that not only the progress of the chemical industries generally, but success individually, is very much promoted by free intercourse and friendly emulation of those connected with them. No doubt when a man spends time, money and labour in improving a manufacture he is entitled to some little monopoly, but the State steps in here and grants it on very reasonable terms. By the new Patent Amendment Act provisional protection for a whole year can be had for the modest sum of five pounds, and this surely is of importance in getting new processes and appliances discussed so as to assess their value, and prevent useless waste of money. I hope that the proprietors of private works and directors of companies will allow, from time to time, young chemists to bring before our Society descriptions of their various processes and methods, as most of our technical dictionaries and encyclopaedias are 10 or 20 years behindhand in their descriptions of manufacturing processes.

CRITICAL EXPERIMENTS ON THE CHLOROPLATINATE METHOD FOR THE DETERMINATION OF POTASSIUM, RUBIDIUM AND AMMONIUM, AND A RE-DETERMINATION OF THE ATOMIC WEIGHT OF PLATINUM.

BY W. DITTMAR, LL.D., F.R.S., F.R.S.E.; AND JOHN M'ARTHUR.

Professor Dittmar said:—A complete account of this investigation was communicated to the Royal Society of Edinburgh, at their last meeting in the summer of this year, in the form of a memoir, which we hope will appear in last Session's transactions or proceedings. My apology for soliciting your attention to-night for a brief summary of the results is that, on the occasion referred to, the memoir was "read" only in the most technical sense, so that what I communicate to you now is really made public for the first time.

The analytical methods referred to in our heading are infected with numerous sources of error, amongst which, until lately the uncertainty of our knowledge of the combining constant Pt played a not unimportant part. This uncertainty it is true has been removed to a great extent by a most meritorious investigation of Seubert's, which is published in

Liebig's *Annalen* for 1881 (vol. 207, pp. 1 *et seq.*). There can be no doubt that his value—Pt = 194·8 (O = 16) is considerably nearer the truth than Andrew's number 198, which until lately was adopted by all chemists. But it does not follow that in, for instance, the analytical determination of chloride of potassium as metallic platinum, the factor 2KCl : Pt = 0·7657, as calculated from Seubert's Pt and Stas' number for KCl, affords a more nearly correct result than even the factor 0·7525, which follows from the old atomic weights, K = 39 ; Cl = 35·5 ; Pt = 198.

The experience of analysts rather goes the other way. This, of course, goes no hair's breadth towards invalidating Seubert's result ; it only shows that those analytical factors which by theory are equal to $K_2 : Pt$; $K_2 : PtCl_6K_2$; $2NH_3 : Pt$, etc., etc., must be determined directly, and separately for the several methods. This is what, in a limited sense, we have endeavoured to do. But a purely empirical determination of the factors would have been of comparatively little use. If, for instance, the analyst's factor for the reduction of platinum to chloride of potassium differs from the ratio 2KCl : Pt, the causes of the difference must be ascertained, and this naturally leads to an inquiry into the true value of the chemist's Pt. We accordingly took up this enquiry, and in this sense our investigation joins on to Seubert's ; which, of course, was welcome to us as an excellent basis for our own work.

In our memoir we begin by detailing the methods which we used for the preparation of the necessary reagents ; on the present occasion I confine myself to a few remarks on what goes universally as *chloride of platinum.*

To the present day I believe a considerable minority of chemists believe that this well-known preparation is simply a hydrate of $PtCl_4$, although it has long been shown that it is chloroplatinate of hydrogen, $PtCl_6H_2$, equal, of course, to $PtCl_4 + 2HCl$, but the 2HCl cannot be removed by heat without at least partial reduction of the $PtCl_4$ to $PtCl_2$.

In preparing our chloroplatinic acid we at first used the well-known aqua-regia process. But the reagent, when made in this way, however carefully, is liable to be contaminated with the nitroso-body $PtCl_6(NO)_2$, which, from a syrupy solution of the crude reagent, sometimes separates out on cooling in small yellow crystals which look almost like a chloroplatinate. On addition of water the crystals are dissolved and decomposed with formation of chloroplatinic acid and evolution of nitrous acid ; but from our experience it appears questionable whether it is possible to completely destroy the nitroso-body by even repeated alternate evaporation with hydrochloric acid and water respectively. We therefore, in the later stages of our research always prepared our reagent by the action on metal of chlorine and hydrochloric acid, as described in our memoir, and also in my "Exercises on Quantitative Analysis," p. 310. After the section on the reagents we pass to a

SERIES OF EXPERIMENTS ON THE COMPOSITION OF CHLOROPLATINATE OF POTASSIUM

as produced under what we may call analytical conditions. In a first set of seven experiments designated as Nos. I., II., III., IV., V., V*a.*, VI., the general *modus operandi* was about as follows :—An exactly known weight of chloride of potassium weighed out as a gravimetrically standarised solution was mixed with a quantity of chloroplatinic acid solution containing an exactly known weight of metal, so adjusted that it was either very nearly equivalent to or slightly in excess over the chloride of potassium. The solutions were in all cases pretty concentrated. Sometimes the precipitate produced was simply allowed to settle, then washed by decanting filtration, first with small instalments of water, then with strong alcohol ; in other cases the reagent-moisture was evaporated to a very small volume and the residue treated with strong alcohol to remove the excess of chloroplatinic acid. From the united filtrates (after removal of the alcohol from the alcoholic part) the platinum was reduced out by hydrogen in the wet way and weighed after ignition ; in the filtrate the small quantity of chloride of potassium which had escaped precipitation was determined as chloroplatinate of potassium, so that the weights of platinum and chloride of potassium in the original precipitate of chloroplatinate could be calculated from the corrected data of the synthesis.

The chloroplatinate precipitate, after having been dried at a definite temperature or successively at a series of temperatures, was weighed and analysed. In some cases only the fixed chlorine and the platinum were determined (to check the result of the synthesis) ; as a rule, however, also the total chlorine and consequently, by difference, the loose chlorine was determined. In a few cases the water, which was found to cling to those chloroplatinates most tenaciously, so that some of it remains even at 150° C., was determined directly by a method detailed in the memoir.

In a special experiment (No. VII.) a very large excess of chloride of potassium was used in preparing the chloroplatinate, and the mode of collecting the latter suitably modified.

In a third set of experiments (Nos. VIII., IX. and X.) the characteristic feature was that, in the preparation of the chloroplatinates a very large excess of chloroplatinic acid was used (about 1·6 times Pt per 2KCl). In the first experiment of this kind (No. VIII.) the two reagents were simply mixed as concentrated solutions, the precipitate was filtered off and washed with, first chloroplatinic acid solution, and with strong alcohol. In other three (IX., XI., and XII.) the mixture was evaporated to a magma, and this, after cooling, first lixiviated with chloroplatinic acid solution, and then washed with strong alcohol (Mr. Tatlock's mode of treating analytically obtained $PtCl_6K_2$). The chloroplatinates of this set showed the remarkable peculiarity that their weights became constant, very promptly, even at the low temperature of 100° C., and that the preparations thus dried contained only minute proportions of water.

In true chloroplatinate of potassium every 2KCl = 149·18 parts are operated with Pt parts—*i.e.*, one atomic weight of platinum. The corresponding weights of platinum in our preparations were as follows :—

Set I. Platinum slightly if at all in excess over the chloride of potassium.—Pt = 195·67 to 196·95 ; mean of 7 results = 196·23.

Set II. The (one) chloroplatinate produced by adding to $PtCl_6H_2$ a large excess of KCl.—Pt = 194·65. This last result, however, is easily explained by assuming that the preparation contained carried down chloride of potassium. Calculating from the loose chlorine we found for 4 × Cl parts of the latter 186·78 parts of platinum and 1·011 times K_2Cl_2 of chloride of potassium, which seems to us to be the correct mode of interpreting the analyses.

Set III. A chloroplatinate (VIII.) made by precipitating chloride of potassium with a large excess of chloroplatinic acid.—Pt = 195·87.

Chloroplatinates made by evaporating chloride of potassium with a large excess of chloroplatinic acid, lixiviating with chloroplatinic acid and then washing *with alcohol.*—Pt = 195·59 : 195·82 : 196·01 : mean 195·81.

In the case of two experiments of Set I. the chloroplatinates obtained, after having been analysed, were *recrystallised* from hot water, and in both the crystals and mother liquors, the platinum, the fixed chlorine and the total chlorine determined. The crystals were found to contain less loose chlorine than twice the fixed, and the weight of platinum combined with 2KCl was lower than that present in the original chloroplatinates. It amounted in one case to 195·48, in another to 195·54 parts. The mother liquors contained free chloroplatinic acid and free hydrochloric acid besides chloroplatinate of potassium. Obviously the original chloroplatinates, in addition to $PtCl_6K_2$, contained surplus platinum in the form of, presumably, $Pt(OH)_6H_2$. By the action of the water part of the chlorine of the $PtCl_4$ was eliminated as HCl and its place taken by an equivalent of OH or oxygen : the free hydrochloric acid formed served to dissolve away the hydroxide of platinum as chloroplatinic acid. Assuming all the surplus platinum to have been dissolved away, the above numbers 195·48 and 195·54 should be close approximations to the true atomic weight of platinum.

No doubt it is the water present as hydroxyl which, in ordinary chloroplatinates of potassium, clings so fast to the salt on drying ; the chloroplatinates made in the Tatlock style are relatively free of such water and consequently presumably of oxidised platinum ; hence we thought the best thing we could do would be to prepare a large quantity of such chloroplatinate, and after having analysed it, to subject it to a series of recrystallisations and analyse the recrystallised products. We were not quite able to carry out our original programme, partly through want of time, but chiefly through want of material. What we did do is stated in our memoir ; suffice it here to say that a salt derived by many successive crystallisations from chloroplatinates X. (I. and II.) gave for 2KCl parts, Pt = 195·60 ; and the chloroplatinate recovered from the mother liquors, after having been recrystallised from hydrochloric acid, gave Pt = 195·37. The mean value derived from the analyses of all our recrystallised salts, as far as we permitted them to vote, was 195·50.

After having arrived at this result, we submitted Seubert's report to a careful critique, which led us to the conviction that his analyses of chloroplatinate of potassium, if properly interpreted, fall in as well, and that his analyses of chloroplatinate of ammonium fall in better, with our number 195·5 than with his own adopted number 194·8 (O = 16).

In regard to our experiments on the chloroplatinates of *rubidium* and *ammonium*, I here satisfy myself with stating that that remarkable tendency of a precipitate of chloroplatinate of potassium to carry down platinum as chiefly hydroxide, if produced in the *absence* of any large excess of chloroplatinic acid, is greatly intensified in the case of rubidium and not by any means absent from the ammonium compound. Rather than doing more I will now pass to what, for my present audience, is the most important part of our work—namely, our

Critical Experiments on Finkener's and Tatlock's Methods for the Determination of Potassium by Means of Chloroplatinic Acid.

Finkener's Method.—As Finkener's method is not much known to British chemists, we begin in our memoir by shortly describing it, assuming, to fix ideas, that we had to deal with a mixture of sulphates and chlorides of potassium, sodium and magnesium.

To determine the potassium a known weight of substance is dissolved in water and the solution mixed with a little more chloroplatinic acid than the potassium demands for its conversion into chloroplatinate, and enough of sulphuric acid to convert all the foreign bases into normal sulphates. The mixture is heated on a water-bath and, if necessary, some water is added to bring all the chloroplatinate into solution. The solution is evaporated on a water-bath to the consistence—after cooling—of a magma. This is allowed to cool, mixed with a sufficiency of ether-alcohol (2 vol. of absolute alcohol and 1 of absolute ether) and allowed to stand, well covered, until the precipitate has settled completely. The precipitate then is washed with ether-alcohol until all that is soluble in this liquid is removed. The residue contains all the potassium as chloroplatinate and most of the sodium, etc., as sulphate. For the determination of the potassium in it Finkener gives us the choice between the following two methods :—

(*a*) The precipitate is heated in hydrogen gas, which reduces the platinum to the metallic state, the sulphates and chloride of potassium are washed away, and the platinum is ignited and weighed.

(*b*) The foreign sulphates are extracted by means of a cold saturated solution of sal-ammoniac, and after their complete removal the residual chloroplatinate (+ NH_4Cl) is ignited in a crucible in an atmosphere of hydrogen gas, so that ultimately a mixture of chloride of potassium, platinum and charcoal (from the filter) remains. The chloride is extracted by water, the platinum collected on a filter, ignited and weighed. In this case, of course, we have the option of determining the chloride of potassium in its aqueous solution, either quite directly or indirectly by determining its chlorine.

Finkener, in his memoir, quotes a number of test-analyses which all gave very fair and some very exact results. But for reducing his platinum weight to K_2O, KCl, etc., he used factors based upon the old atomic weight of platinum, and these factors, as we now know, were too low, the one corresponding to $K_2O:Pt$ by nearly two per cent. of its value. Hence the precision in his results must have been due partly to a compensation of errors. We have made a very large number of experiments with the view of ascertaining the nature and magnitude of these errors, and, if possible, eliminating them by suitable modifications. Our general method was this :—

Starting with a synthetically prepared solution containing an exactly known weight of chloride or sulphate of potassium, associated with approximately known quantities of sulphates or chlorides (or both) of sodium or magnesium (or both)—the proportion of impurities was made to vary from nil to many times the weight of the potassium salt—we applied the Finkener process, and, besides weighing the platinum, which, according to the theory of the method, should measure the given potassium, determined the small quantities of the latter metal which had passed into the ether-alcohol or other liquors obtained. In the earlier stages of the research we generally applied the sal-ammoniac form of the process, and always took care to collect, weigh and *analyse* the crude chloride of potassium produced. No test experiment of this kind was accepted as complete and satisfactory unless all the several instalments of potassium when added together came up, as nearly as possible, to the weight of potassium started with in the synthesis. Even in our memoir we give only a very condensed report on our work ; on the present occasion it would be a mistake to do more than formulate our conclusions. One of these is that the Finkener process (sal-ammoniac form) affords an excellent means for collecting and concentrating even the minutest quantities of potassium diffused throughout a mass of sodium or magnesium salts. Only, to obtain exact results, one must take care to work up the sal-ammoniac liquors for potassium, and supposing all the potassium to be collected as chloride, this chloride must not be accepted as pure KCl (which it never is), but be analysed for potassium by, say, the Fresenius method, which in such cases is perfectly reliable and probably the best that could be employed. In this manner minute percentages of potassium, which would simply escape any other method and not be found at all, can be determined with a (for such cases) high degree of relative precision. The Finkener process, therefore, affords an excellent means for testing other forms of the chloroplatinate method by determining the small quantities of potassium which slipped through their meshes. In this sense among others we have used it extensively. Passing now to the process as a means of determining relatively large percentages of potassium, I cannot do better than shortly describe the form of the process which we adopted finally for such purposes.

The substance solution is mixed with a volume of standard sulphuric acid so adjusted that it little more than suffices to substitute a half SO_4 for every Cl of the clorides, and with about 1·25 times the calculated volume of chloroplatinic acid solution, and, if necessary, enough of water so that the whole of the chloroplatinate of potassium passes into solution at a boiling heat. The solution is then evaporated to a magma and next mixed with, say, 20cc. of absolute alcohol and allowed to stand for five minutes (covered, of course). 10cc. of ether are now added and the mixture is allowed to stand for half-an-hour under a small bell-jar on a ground glass plate, when the mixture is ready to be filtered. The precipitate, however, in addition to chloroplatinate of potassium, contains a small quantity of foreign chloroplatinates, which, as we found, can be eliminated by what we have come to call *re-crystallisation*. The mixture (of sulphates and chloroplatinate), after having received a final wash with pure *ether*, is allowed to dry up in the air; it is then re-dissolved in hot water and re-Finkenerised; the surplus platinum is retained in the mother liquor. For a time we thought that the addition of a few drops of sulphuric acid would be an improvement, as giving the sodium, etc., a better chance of coming out as sulphate; but direct experiments showed that the results then became less exact. The purified mixture is dissolved in hot water, the solution transferred to an Erlenmeyer flask, the platinum reduced out in the wet way (see Dittmar's "Exercises in Quantitative Analysis," p. 28), collected, ignited and weighed.

The weight when multiplied with 0·76084 gives a very close approximation to the weight of chloride of potassium to be determined. This factor was deduced from a special series of test-analyses, to which I shall again have to refer after having treated of the

Tatlock Method.—This method, before an audience of Glasgow chemists, need not be described, but I doubt whether its essential points are as generally appreciated as they ought to be.

According to Tatlock, to determine the potash in a mixed potash salt, a known weight is dissolved in water and next evaporated down to a magma with a certain prescribed quantity of chloride of platinum, which is far in excess of what would be needed theoretically even for the conversion of pure chloride of sodium into chloroplatinate. The residue is allowed to digest in a certain proportion of five per cent.* platinum solution, so adjusted that in the case of pure NaCl a 17 per cent. solution of platinum is produced. This liquor is allowed to act for an hour and the precipitate is then washed with, first, small instalments of the five per cent. reagent, and finally with 95 per cent. alcohol. It is then dried at 100° and weighed. The weight multiplied by 0·3056 gives the weight of chloride of potassium to be determined.

Tatlock's method at first sight would appear to waste an unnecessarily large amount of platinum solution. Why not, one might say, separate out the potassium with a moderate excess of platinum from a very concentrated solution, wash the precipitate very cautiously with small instalments of water and ultimately with alcohol to get it ready for the drying chamber? We have tried this modification, but have found that nearly 10 per cent. of the potassium escapes precipitation. If Tatlock's directions be strictly followed the loss is far less.

It will also *not* do to continue the washing with chloride of platinum solution until every trace of sulphate is proved to be removed. With substances rich in SO_3 this cannot be accomplished without losing a considerable fraction of the potassium; with Tatlock's *modus operandi*, on the other hand, the sulphuric acid, contrary to what some might expect, goes almost completely into the alcoholic washings.

According to our determinations, 100grms. of a five per cent. solution of chloroplatinic acid dissolve, in the cold 0·23grm. of chloroplatinate of potassium, hence Tatlock's method, in all cases, must necessarily leave some of the potassium in the filtrate. But the quantity of potassium thus lost, in most practical cases, is small, and is compensated for to a surprising extent by the positive errors inherent in his method.

At a time when we had not yet arrived at this conviction, we instituted a special series of test analyses for ascertaining what results the Finkener and the Tatlock methods respectively would bring out with mixtures of chloride of potassium, chloride of sodium, and sulphate of magnesia, containing respectively 95, 82, and 33·3 parts of chloride of potassium in 100 of anhydrous mixture.

A known weight of pure chloride of potassium was weighed out, dissolved in water to a known weight, and quantities of this standard solution representing convenient definite weights of KCl weighed out immediately in so many different bottles. On the other hand, pure—*i.e.*, potassium free—standard solutions of chloride of sodium and of sulphate of magnesia were prepared and kept ready for use. To produce, for instance, a solution of 95 per cent. salt, the contents of one of the KCl bottles was mixed with the proper volumes of magnesia and chloride of sodium solution. In this manner we produced eight solutions of each kind; four were analysed by means of our form of the Finkener method, the other four according to Tatlock. In the case of the Tatlock analyses, we always determined the potassium left unprecipitated by means of Finkener's method, and reduced the chloroplatinate, after having weighed it, with hydrogen in the wet way, and weighed the platinum, so that each of our analyses afforded the data for a calculation of the quantity of chloride of potassium combined in the precipitate with 2KCl parts of chloride of potassium —*i.e.*, for what, by theory, should be the atomic weight of platinum. The several values for "Pt" thus obtained lay remarkably close to 196. The mean of the Finkener experiments was 195·98; that of the Tatlock experiments was 196·25. For the reduction of Pt to 2KCl, the factor 0·76117; for that of $PtCl_6K_2$ to K_2Cl_2, Mr. Tatlock's factor, 0·3056, was employed, and in both series a satisfactory agreement between analysis and synthesis attained. At the end of the work, however, we

---

*Meaning a solution containing 5grms. of metallic platinum per 100cc.

calculated the factors from our own experiments, and found for the factors corresponding theoretically to K_2Cl_2 : Pt and K_2Cl_2 : $PtCl_6K_2$ the values 0·76084 and 0·30627 respectively. On recalculating all our analyses with these factors and comparing the results with the values demanded by the synthesis, we found that in each of the two series one experiment was infected with an exceptionally large error, amounting to about 2mgrs. in each case. All the rest of the errors were far less. In the Tatlock series they were as follow :—

	95 per cent	82 per cent.	33 per cent. Salt.
Errors	0·26 to 0·28	0·06 to 0·49	0·03 to 0·1mgr.
Per about	0·61	0·52	0·215grm. of KCl.

In the Finkener series they were respectively :—

	0·07 to 0·5	0·17 to 0·33	0·18 to 0·7mgr.
Per about	0·75	0·65	0·26grm. of KCl to be determined.

The methods, as we see, are about at a par in point of precision ; but how far may the percentage of potash in a salt sink before the Tatlock method becomes inapplicable ? We made a special series of of experiments in this direction, and found that the line must be drawn somewhere below the 10 per cent. salt. With a 10 per cent. salt, while the Finkener method gave exact results, the Tatlock gave a deficit of about 2 per cent. of the quantity to be determined—9·8 instead of 10, which is still pretty fair.

Summary of Results.

(1.) The value Pt = 194·8 (O = 16), which Seubert deduced from his analyses of chloroplatinates, is too low ; his own analyses, if properly interpreted, show that the true value lies, by a considerable fraction of a unit, higher.

(2.) According to our own analysis of chloroplatinate of potassium, the true "Pt," though, perhaps, a shade below, lies close to 195·5. This number falls in perfectly well with Seubert's analyses likewise, and consequently *at present* constitutes the most probable value of the constant.

Method.	Symbols.	Theoretical Factors.			D. and McA.'s Empirical Factors.	Notes.
		Values Calculated for				
		Pt = 194·8	195·5	196		
Ta.	$2KCl : PtCl_6K_2$	0·30707	0·30665	0·30633	0·30627	(1)
Ta	2KCl : Pt	0·76571	0·76307	0·76112	0·76016	(2)
F	2KCl : Pt	0·76571	0·76307	0·76112	0·76084	(1)
N	$2NH_4Cl : PtCl_6(NH_4)_2$	0·24123	0·24081	0·24057	0·2389	(3)
N	$2NH_4Cl$: Pt	0·54934	0·54737	0·54598	0·5459	(4)

Notes.—(1) Refers to the chloride of potassium in the substance.

(2) Refers to the chloride of potassium in the chloroplatinate-precipitate.

(3) and (4) Refer to the sal-ammoniac to be determined, not to that contained in the chloroplatinate-precipitate.

(3.) Taking "Pt" as meaning the number which must be substituted for Pt in the calculation of the ratios, $2KCl : PtCl_6K_2$; 2KCl : Pt ; $2NH_4Cl$: Pt, etc., in order to obtain the correct factors for reducing analytically obtained chloroplatinate or chloroplatinate-platinum to chloride of potassium, etc., even our number, 195·5, is too low ; 196 affords in general a better approximation. But Pt, if taken in this sense, is no constant at all. Those factors must be determined quite directly by standard experiments. The results of our own standard experiments are given, and contrasted with the theoretically calculated ratios in the above table. The entries "Ta" refer to Tatlock's methods ; the entries "F" to our own form of Finkener's method : the entries N to the customary platinum process for the determination of ammonia

FREE ACID IN SUPERPHOSPHATES.

BY WILLIAM W. MELLON.

It is well known that superphosphates and similar dissolved manures invariably contain a certain amount of free acid, but some diversity of opinion exists with regard to the amount usually present and the composition of this constituent of manures.

Having estimated the free acid present in a large number of samples of manures during the last four and-a half years the results obtained are offered as a contribution on the subject.

The estimations were performed by titrating with standard alkali a solution of the manure containing about 1grm. of the sample in 100cc., to which a few drops of methyl orange had been added. Monobasic phosphate being neutral to methyl orange, the amount of standard alkali required to neutralise the solution is equivalent to the free acid present. For convenience in comparing the results the free acid is stated as H_3PO_4.

The average amount found in 485 samples of manures of various kinds examined by this method was equal to 8·54 per cent. H_3PO_4 ; the highest being 16·36 per cent., and the lowest 2·36 per cent.

The solutions of manures in which the free acid was determined were obtained by stirring up 10grms. of the sample with water in a beaker and transferring to a 500cc. flask. The flask was filled to the mark with water, allowed to digest for a couple of hours with occasional shaking, and filtered. (Method A.)

Several methods of extracting the soluble portion being in use in the analysis of manures, a number of experiments were performed in order to ascertain if the percentages of free acid and "soluble phosphate"* were affected by the method of extraction adopted. With this object in view the free acid and soluble phosphate were estimated in solutions of manures obtained by Method A, and also in solutions obtained by the method adopted by the Association of Official Agricultural Chemists for the season 1884—85.† About 2grms. of the sample are washed on a filter with small successive quantities of water, the residue transferred to a beaker, rubbed to a paste with a rubber-tipped rod, washed back on to the filter and washed thoroughly. (Method B.)

The results, which are given in the following table, show that the amount of free acid is generally higher in the B solutions, this result being more noticeable in manures made from roughly ground materials, or when an insufficient quantity of acid had been used in the first place to dissolve the phosphate, and is probably due to the rapid removal of the acid solution in the filter from the undissolved phosphate with which it was in contact.

With respect to the soluble phosphate the experiments show that the B solutions give slightly lower results with manures which do not contain ferric oxide—such as dissolved bones and bone ash, and higher results with mineral superphosphates containing ferric oxide.

The larger amount of phosphoric acid found in the B solutions of mineral superphosphates is due to the fact that ferric phosphate is soluble only in somewhat concentrated acid solutions.

On treating the sample, with small successive quantities of water, as in Method B, filtering after

---

*Tricalcic phosphate rendered soluble, is meant by the term "soluble phosphate."

†Chemical News, 51, 19.

each addition, the ferric phosphate is carried through the filter in solution and its phosphoric acid included in the soluble, whereas the dilution required by the other method before filtering precipitates a portion of the phosphoric acid as ferric phosphate, which is included in the insoluble phosphate.

The amount of free acid in manures is obviously an important factor in determining their condition, yet no definite amount can be assigned in all cases as a limit which should not be exceeded, as the maximum quantity that may be present in a manure without impairing its condition varies with the raw phosphate used.

The average amount of free acid found in well-dissolved manures made from various phosphates is given in the following table. The manures were all in a dry friable condition, and the mineral phosphates used were ground so that 96 per cent passed through a sieve of 60 meshes to the inch.

Phosphate.	Free Acid as H_3PO_4.	Insoluble Phosphate %
Ground bones	2·81	4·82
Bone ash	7·55	1·91
Belgian phosphate	7·26	1·85
Port Royal „	9·91	1·57
Bull River „	10·21	2·33
Morgan River phosphate	10·32	1·68
Somme phosphate	12·56	1·62

The amount of free acid in manures is also to some extent affected by the strength of the acid used to decompose the phosphate.

With regard to the quantity of acid employed the manufacturer will, as a rule, use as much as is consistent with a dry product; but, other things being equal, the maximum quantity of o.v. can be used only when it is diluted to the strength best adapted to the phosphate under treatment.

This is illustrated by the following experiment with Canadian apatite:—Three portions of a sample of Canadian apatite were each treated under precisely similar conditions, with 63 per cent. o.v. diluted to 108°, 112 and 120° T. On testing the resulting superphosphates the following results were obtained:—

63 per cent. o.v. at	108° T.	112° T.	120° T.
Soluble phosphate	28·06	27·50	21·63
Free acid „ as H_3PO_4	10·42	11·46	17·24
Condition of manure	Good	Fair	Damp

A number of samples were examined, and an effort made to determine the composition of the free acid always present in manures.

It seems to consist mainly of phosphoric acid, with smaller amounts of hydrofluosilicic, hydrofluoric and (occasionally) sulphuric acids. The latter was found only in damp samples containing a large amount of free acid. It was detected by treating the sample with methylated spirits on a filter fitted with a Piccard's filtering tube, the filtrate was evaporated to dryness, water containing a few drops of HCl added and the sulphuric acid precipitated with baric chloride. The conflicting opinions held with regard to the presence of free sulphuric acid in manures may probably be attributed to the absence of a reliable method of estimating or detecting free sulphuric and phosphoric acids in presence of each other, in solutions which also contain soluble sulphates and phosphates.

The method frequently proposed for the estimation of free sulphuric acid in presence of soluble sulphates, which depends on the precipitation of the sulphates only on the addition of alcohol to the solution, is inapplicable in the presence of monocalcic phosphate. In the presence of this salt the alcohol precipitates not only the sulphates, but also more or less of the free sulphuric acid, which combines with the lime of the monocalcic phosphate, free phosphoric acid being liberated.

In order to test the accuracy of the method 3cc. of normal sulphuric acid = 0·147grm. H_2SO_4 were run into a somewhat concentrated solution of superphosphate, and about seven times its bulk of methylated spirits was added. After standing two hours the alcoholic solution was filtered, the filtrate evaporated to dryness, some water and a few drops of HCl were added, and the sulphuric acid in the solution estimated with baric chloride. The amount found was equal to 0·048grm. H_2SO_4, showing that 0·099grm., equal to 67·35 per cent. of the sulphuric acid added, had been precipitated on the addition of alcohol. Similar results were obtained when absolute alcohol was substituted for the methylated spirits; the free sulphuric acid precipitated in a number of experiments varied from 42 per cent. to 83 per cent. of the sulphuric acid added to the solution. This process is therefore incapable of demonstrating the absence of free sulphuric acid in manures.

On the other hand, the method used for the detection of free sulphuric acid in presence of sulphates, which relies on the blackening of the residue obtained on evaporating the solution to dryness with a little cane sugar, cannot be employed in presence of free phosphoric acid, which also decomposes cane sugar with formation of a black residue.

The presence of free hydrofluosilicic and hydrofluoric acids in manures seems to have escaped observation. In the ordinary course of manure analysis, in which the moisture is determined by heating the sample for several hours in the water oven, they are volatilised and reported as "moisture." The average amount of volatile free acids found in 14 samples was equal to 2·30 per cent. H_3PO_4—the highest being 3·96 per cent., and the lowest 0·96 per cent. They were estimated by evaporating a solution of the manure to dryness in a platinum basin, the residue was dissolved in water to which a known amount of standard acid had been added, and the solution titrated with standard alkali. The loss of free acid on evaporation equals the total volatile acidity, stated as H_3PO_4. The free hydrofluosilicic acid was estimated by evaporating to dryness a solution of the manure to which some potassic sulphate, neutral to methyl orange, had been added, the residue was dissolved in standard acid and titrated as before. The increase in the amount of free acid as H_3PO_4 after evaporation with potassic sulphate, as compared with the amount found on evaporating the solution of manure alone, is equivalent to the free hydrofluosilicic acid present.

The amount found in the few samples tested comprised about two-thirds of the total volatile acidity.

The above results were obtained from manures manufactured by Mr. G. H. Anderton, Howden, Yorkshire, to whom the writer is indebted for the facilities afforded in carrying out the experiments.

The Second Meeting of the Fifth Session of this Section was held in the Rooms, 14, St. Andrew Street, Edinburgh, on Tuesday, 6th December, 1887.

MR. E. C. C. STANFORD, F.C.S., IN THE CHAIR.

THE SUPPLY OF ALCOHOL FOR MANUFACTURING PURPOSES.

BY D. B. DOTT, F.R.S.E., F.I.C.

It is now over thirty years since the Act of Parliament was passed permitting the use of duty-free methylated spirits, and we have become so accustomed to the idea of that familiar mixture that it is difficult to imagine things being otherwise—nearly as difficult possibly as it would be to persuade the Revenue authorities that a change in their system is desirable. Yet the systems in vogue in other countries have been altered, sometimes for the better, and our own Government may one day see its way to amend the law regulating the use of alcohol in the arts and manufactures. Presumably everyone knows how the law at present stands. The original Act has been amended by two subsequent Acts, and there are several General Orders of the Board of Inland Revenue bearing on the subject, but the net result of the regulations may be shortly stated. Every form of ethyl alcohol used or sold in the country must pay duty calculated on its equivalent in proof spirit, but to encourage manufacturers a mixture of alcohol with 10 per cent. of wood naphtha is allowed to pass duty free. This naphtha is often called methyl alcohol, but it contains so large a proportion of acetone, along with higher ketones, methyl acetate, allyl alcohol, and malodorous pyroligneous substances, that it can hardly be called even crude methyl alcohol. An admixture of pure methyl alcohol would be no barrier to the use of the mixture as a beverage. Wherefore the Excise will only permit the use of a decidedly crude and impure wood naphtha for methylating, and a sample of the naphtha proposed to be used must first be approved by the Chemical Department at Somerset House. After being passed, the naphtha is kept under official lock and key, and only allowed to be used for mixing in presence of officers of Inland Revenue. The resulting methylated spirit has a disagreeable taste and odour, and always more or less colour, which increases on keeping. It is, of course, entirely illegal to submit the spirit to any process of purification, even the preparation of anhydrous methylated spirit being held to be a clear breach of the law. The mixed spirit can only be used in such branches of manufacture as are approved by the Board. Its use is not allowed in the preparation of compounds from which alcohol can easily be obtained. For instance, if a simple process for converting ether into alcohol were known, it is certain the Board would not permit the use of methylated spirits in the preparation of ether.

We have often heard of the great benefits that have accrued by the wise and beneficent legislation which authorised the use of methylated spirits, but much might be written on the extent to which manufacturers have suffered by being compelled to use that same spirit while neighbouring nations had a supply of pure alcohol at or near the same price. I have not sufficient acquaintance with manufactures in general to go fully into this question, but can only touch upon those points which are more within my own knowledge and experience. It has first to be noted that miscible naphtha is a more expensive article than rectified spirit, so that (apart from duty) methylated spirit costs more than pure alcohol. Then it must be remembered that for many purposes the 10 per cent. of naphtha is simply 10 per cent. of useless matter. That is to say, that in these cases methylated spirit would require to be 10 per cent. cheaper than the pure spirit in order to put them economically on a par. So far as I know, there is no purpose for which methylated spirit is so well adapted as is pure spirit, and we have all grades of unsuitability up to those cases in which it cannot be used at all. Methylated spirit is generally supposed to be specially suitable for making varnishes, yet I have heard of a fastidious gentleman who insisted on the polish applied to his furniture being prepared with pure alcohol, on account of the bad smell of the usual preparation. For purposes of extraction, purification by crystallisation, and the like, methyl spirit is very objectionable, because of the persistent empyreumatic odour it leaves on evaporating, which odour it is difficult and sometimes impossible to get rid of. Again, when we employ rectified spirit as a solvent we know that we are using what is to all intents and purposes a mixture of ethyl alcohol and water, but when we employ methylated spirits we are using a mixture of several, and to some extent unknown, solvents. In certain operations that is a matter of real importance. In the preparation of chloroform methylated spirit is not so ill adapted as might at first be supposed. A certain amount of chloroform is formed from the acetone present in the naphtha, and by special means of purification a product is ultimately obtained which cannot be distinguished from that prepared from pure alcohol. Yet there can be no question that, *cæteris paribus*, pure alcohol would be a preferable raw material even in this instance, as there would then be no suspicion of certain impurities, and the medical profession would have more confidence in the compound. In the formation of ether by the action of sulphuric acid on alcohol at a high temperature, the methylated is a poor substitute for the pure spirit. Not only does the product contain a certain amount of ethyl oxide in solution, but secondary products are formed which render the ether unsuitable for inhalation and internal use, though it may be employed for local anaesthesia. On the other hand, there are manufactures in which the products formed from the naphtha are so difficult to separate from the alcoholic product that the chemist who has only methylated spirit at his disposal is hopelessly handicapped as compared with the chemist who has pure alcohol to work with. For instance, when chloral was first introduced into medical practice it was found impracticable to obtain a satisfactory product by the action of chlorine on methylated spirit, for which reason principally chloral did not become an article of British manufacture. Doubtless one who was well acquainted with a great variety of manufactures could frame a much stronger indictment against methylated spirits than can I, but what has been said is sufficient to show that if the chemist could obtain pure alcohol free of duty it would be an immense advantage. In this connection it may be interesting to quote a few sentences from an article* by Dr. Squibb, who was actively engaged in the investigations which preceded the passing of the American Spirit Law, and who himself uses annually a large quantity of alcohol in his pharmaceutical processes:—"The proposed law proceeds on the theory that this methyl-alcohol once added to the clear spirit, permanently and irrecoverably spoils it for drinking purposes. This is a great fallacy which should be clearly recognised at the start, for the methyl-alcohol can be taken out with comparative ease, and the proposed law acknowledges this by forbidding its being taken out and by providing a penalty against taking it out . . . . There is probably not a single use to which alcohol is put that would not be more or less obstructed and hurt by the presence of the methyl—just as every adulterated substance is injured by the adulteration—while in a very large number it would be more objectionable than in drink; and for a still larger number of the better and more important uses methylated spirit could not be used at all. . . . . Again, it is not conducive of true economy and fair dealing to attempt by law to damage the purity of, or to spoil or defile any substance for any purpose, and all such attempts must lead to loose principles of action and to various forms of fraud."

The question then arises—Can any method be devised by which a chemical manufacturer might be allowed the use of duty-free alcohol in his manufactures? Speaking generally, there are two ways in which this could be done:—1st. The manufacturing operation might be conducted "in bond," nothing being allowed to go in or out without the intervention of the Excise officials. 2nd. A drawback of the full amount of duty might be allowed on all alchohol which the authorities were satisfied had been converted into compounds from which alcohol could not be recovered. Mr. John Williams (of Messrs. Hopkin Williams) has endeavoured to induce the Inland Revenue authorities to consent to the preparation of absolute alcohol "in bond," but so far without success. At present it is impossible to produce absolute alcohol remuneratively in this country, for the obvious reason that duty has to be paid on the alcohol, which is inevitably lost in dehydrating, while the imported article escapes that part of the tax. If the Excise authorities can hardly be persuaded to give their consent in such a simple case as that of absolute alcohol, it would be difficult, indeed, to induce them to consent to cases in which more or less complicated compounds resulted. They would live in a perpetual dread that alcohol was escaping them in some form or other, and so evading duty. Assuming an operation which could be performed in a short time before an Excise officer, or which could be performed under official lock and key, and in which all the alcohol as such was completely destroyed, there would be no obvious reason why the duty previously paid on the alcohol should not be recovered. Such a case, however, is entirely exceptional, if not merely hypothetical. As a rule, a considerable amount of pure alcohol is recovered in any chemical operation in which it is used. That would require to be checked, and, along with the examination of the other products, would throw an amount on the Department which would be fatal to any such method of procedure. Conceivably a workable plan for the use of duty-free alcohol in manufactures might be devised, if protected by sufficient regulations and penalties, but it is hardly within the region of present practical politics.

In considering whether there is any other way of reaching the desired end, we naturally turn to the latest legislation on the subject—namely, the new Spirit Law of Germany, the provisions of which are, briefly, as follows:—The *denaturirte spiritus*, which corresponds to our methylated spirit, is prepared by adding to 100 parts of alcohol 2 parts of wood spirit and 1 part of pyridine bases. Tests are given to define the quality of these substances. The wood spirit is examined as to colour, specific gravity, boiling point, mixibility with water, content of acetone, and behaviour with bromine; the mixed pyridine bases are examined as regards colour, behaviour towards cadmium chloride, boiling point, miscibility with water, contained water and volatility. Having put this paper together on rather short notice, I have not had time to prepare a sample of this German mixed spirit. I should think, however, that it must be quite as disagreeable to the taste as our own methylated spirit, while for most manufacturing purposes, the 2 parts of naphtha and 1 part of mixed pyridine bases would be far less objectionable than our 10 per cent. of naphtha. But the most important difference between the German law and our own is this: that while our Board of Inland Revenue has one hard and fast rule from which no departure is permitted, the German Customs make many concessions and exceptions for the convenience of manufacturers, and to the benefit of the national trade. For instance, the manufacturers of fulminating mercury are allowed a mixture of alcohol with $\frac{1}{2}$ per cent. turpentine or 0·025 per cent. bone oil. Makers of aniline colours are allowed a mixture containing 0·025 per cent. bone oil. For the preparation of the alkaloids, spirit with $\frac{1}{2}$ per cent. of turpentine or 0·025 per cent. of bone oil is permitted. Similarly, for the preparation of chloroform, iodoform, ether and chloral, the mixture with 0·025 per cent. of animal oil is permitted. For the manufacture of tannin, salicylic acid and salicylates, 10 per cent. of ether is added to the alcohol. Makers of white lead and acetate of lead are allowed the bone oil mixture. The stock of alcohol in the German pharmacies was measured some time ago by the Customs authorities, with the intention of allowing the pharmacists untaxed alcohol, but I have not been able to ascertain whether that provision is to be continued. It is certain that some such arrangements as those above noted would be very advantageous to our British manufacturers. It is equally certain that the Revenue Department would look upon them with great disfavour and regard them as dangerous, not only because it is a conservative department, but also because these mixtures could more readily be purified and rendered drinkable than their well-tried methylated spirit. I believe, however, that these German rules proceed on a good principle, and that similar regulations might be introduced in our own country

---

* Ephemeris, ii. 498.

with benefit to trade and no loss to the Revenue if properly safeguarded.

I venture to suggest a method which meets most of the objections to the use of ordinary methylated spirits, and which I think might be made acceptable to the legislative authorities. Let a second quality of methylated spirits be legalised, to be used only by licensed manufacturers. This sprit would be prepared by mixing alcohol with 5 per cent. of commercially pure methyl-alcohol. Such admixture would not interfere with the use of the alcohol for almost any purpose. On the other hand, it would be difficult to separate and could easily be detected by analysis, so that the fraudulent disposal of the spirits would be extremely difficult. Of course, the removal of the spirit from one place to another would only be accomplished by permit, and anyone other than a licensed manufacturer having such spirit in his possession would be liable to a heavy penalty. It might be found desirable to restrict a manufacturer to only one kind of the methylated spirit: or, at any rate, not to allow the use of both kinds in the same premises. A doubt might arise as to whether it would be permissible to use the finer methylated spirit and alcohol in the same premises, but I think if any improper use of the spirit was made severely punishable, there would be little danger of the Revenue suffering. If the State could see its way to legalise this superior quality of methylated spirits, then it would be free to deal with the ordinary methylated spirits, and by adding poisonous pyridine bases or otherwise, so increase its disagreeableness as a drink that a peculiarly objectionable form of illicit traffic would be greatly reduced. Such is a brief outline of a scheme which I believe to be quite practicable, and which, if worked out in detail and legalised, would be decidedly beneficial to the manufactures of the country.

DISCUSSION.

Mr. Stanford said that this was a subject which had created a great deal of talk both on this side and the other side of the Atlantic, where they also complained of the duty on spirit. He did not see—and he had expressed the view repeatedly—any valid reason why manufacturers should not have duty-free spirit when it was necessary for the manufacture of fine chemicals. As for the idea entertained at the time by Messrs. Hofmann, Graham and Redwood—*i.e.*, that the addition of methylated alcohol of a very disagreeable character would prevent the drinking of the spirit—it was known by everyone that this view was entirely out of the question, as he did not believe it was possible—or scarcely possible—to add anything to the spirit nasty enough to prevent men from drinking it.

Mr. Beilby considered that this was a subject on which the Society should use its influence as a Society, and he would propose that it should take up this subject and make such representations to the proper authorities as would bring the matter under notice again in a proper and efficient manner. He moved, therefore, that the matter be referred to the Committee of the Section for consideration.

Mr. D. B. Dott, in seconding the motion, said it would be preferable to have the use of duty-free spirit if the Government could be persuaded to grant that. But perhaps some alternative scheme, such as he had proposed, might be conceded with greater readiness by the Government, and this would be a step in the right direction, although not so good as having command of pure alcohol for manufacturing purposes.

NOTE ON THE ACTION OF BLEACHING AGENTS UPON WRITING-INK AS A MEANS OF DETECTING FRAUD.

BY ROBERT IRVINE, F.R.S.E., F.C.S.

It is well known that ordinary writing is easily removed when it is acted upon by bleaching agents. Advantage is taken of this fact by unscrupulous persons desirous of altering documents, cheques and banknotes, for improper purposes; hence the number of fugitive inks and supposed untamperable papers in use to meet this difficulty.

A curious and interesting case of supposed fraud came under my notice in the form of a document, which was written upon the fly-leaf or second page of a sheet of legal paper: the margin of the first page containing the stamp, date and water mark of a will purporting to have been written about twenty years ago. The document or will was thus written upon paper bearing both on stamp and in watermark a date which gave it the semblance of age. The appearance of the document gave rise to suspicion, and I was asked if it was possible to tell the age of the writing, and if the writing had been executed at one and the same time, and if so at what time?

This was, of course, impossible, as I was not allowed to treat the document itself; I had, therefore, to make experiments upon writings the dates of which I knew.

I selected writing one day, six months, twelve months, two years, six years, fourteen years and twenty-two years old, and exposed these writings to the action of a very dilute solution of ordinary bleaching powder in water; the specific gravity was about 1001. In six minutes the newly-written matter had disappeared; in from nine to twelve minutes the writing of six months ago had disappeared; in twenty minutes the writing of two years had partly disappeared: in a like time the writing of six years ago was not greatly affected; fourteen years ago very slightly: and twenty-two years hardly affected at all (indeed old writing seems hardly affected by such a weak solution, even after hours' exposure).

Peroxide of hydrogen acts more slowly, but gives more definite results. Other reagents give effects which help (although sometimes in a contrary manner to that I have indicated) to establish the fact that ordinary writing-ink, which is a compound of gallic and tannic acids with proto-salts of iron, becomes more stable (presumably by oxidation), and consequently is less or more affected by chemicals, which act upon the organic colouring matter of the ink. There are great varieties of writing inks, chromium and vanadium salts being sometimes substituted for the iron salts. There are also black and coloured inks, prepared from coal-tar dyes; but thinking it highly improbable that any documents intended for preservation would be executed in such evanescent inks, I did not investigate their behaviour under such treatment. When ink is thus bleached or apparently removed most of the iron contained in the compound remains mordanted with the fibres of the paper; consequently, writing so tampered or dealt with can be restored by the application of gallic or tannic acid. The writing is thus reproduced almost in its original depth of colour. It is delicate work (especially in the civil legal aspect of the case to which I have referred) to determine in a reliable manner the age of any particular writing, and it is necessary that the following precautions be carefully observed:—1. The inks must be those known as ordinary writing-inks prepared from iron and chromium salts and galls. 2. Writing dried by means of blotting paper is naturally more easily removed than writing which is allowed to dry on the surface of the paper; and light writing is somewhat more easily removed than coarse and heavy writing. 3. The bleaching solution must be exceedingly dilute, otherwise the action is so rapid and powerful that both old and new writings are removed almost simultaneously. 4. The action must be carefully watched so as not to be too long continued. Lastly, very old writing which has become brown by age, although it resists the action of weak solutions of bleaching powder and peroxide of hydrogen, will show signs of giving way almost instantly when acted upon by diluted nitric, hydrochloric and oxalic acids.

Although I have only made use of a well-known process and materials to obtain the results I have indicated, still I think such a simple means of detection may act as a check to frauds which are becoming only too common. There was a most interesting paper read before the Literary and Philosophical Society of Manchester in the Session of 1879 and 1880, by Mr. W. Thomson, F.R.S.E., which I commend to the study of anyone wishful to carry this investigation further than I have been able to do. In it the author gives many curious and interesting facts in connection with the behaviour of writing inks under the influences of various chemical compounds.

NOTE ON SACCHARINE.

BY D. A. SUTHERLAND, F.I.C., F.C.S.

It might be as well for me at the outset once more to call attention to the spelling of the commercial name of this substance—saccharine, not saccharin—as I observe in certain notes recently published in this country this latter wrong spelling is adhered to.

Saccharin was discovered by Peligot,[*] and is obtained by boiling invert sugar, dextrose or lævulose with lime, and is also obtained from molasses of beet sugar. Its taste is not sweet, but saline and bitter. Its formula, according to Scheibler,[†] is $C_6H_{10}O_5$.

Saccharine, which is the subject of these few notes, was discovered by Fahlberg and Remsen in 1879, and is chemically benzoylorthosulphonic imide.[‡]  $C_6H_4 <^{CO}_{SO_2}> NH$. It is, as you know, a toluene derivative prepared from coal tar. It is unnecessary for me to refer to its manufacture and numerous uses; these have already been most completely described in our Journal by Ivan Levinstein,[§] and more recently by the distinguished discoverer, Dr. Constantin Fahlberg.[‖]

I desire to note briefly one or two points which so far as I know have not been much commented on. The action of heat, the percentage of ash, and the tests.

Firstly, I would note that there is considerable difference between the samples of saccharine in the market. Within the past month or two the makers, Messrs. Fahlberg, List & Co., have intimated that they can supply orders for any quantity up to one ton.

I noticed a discussion in a chemical journal a week or two ago, as to the percentage of ash on ignition. One observer[¶] notes results varying from 0·6 to 2·9 and 6·6 per cent., and another observer[**] notes 6·67 per cent. Other statements were made, some of which I will refer to in this paper, but it is to be regretted that the acidity was not given in each case.

Having in hand three samples of saccharine, I resolved to see what difference, if any, there was between them and those above referred to.

The samples were obtained as follows:—I. From Germany; II. From druggist in usual way; III. From Messrs. Wilson, Salamon & Co., the London agents, and I would here like to acknowledge their frankness and courtesy in supplying samples and in giving any information.

Action of Heat.—2grms. of each sample were treated at 100° C.: indeed the temperature (maintained with steam) rarely exceeded 95° at any time.

Contrary to the statement in the journal referred to—viz., that "a temperature of 100° C., even if maintained for some time, has no perceptible effect on saccharin(e); it loses no weight, and undergoes no physical change"[††]—in each case my samples, almost instantly, on placing them in the heater gave off a slight sublimate which adhered to the watch-glass with which they were covered. Moreover, after three hours, had decreased in weight as under:—

Sample I.—1·75 per cent. loss } Other samples after
„ II.—2·05 „ „ „ } 24 hours—loss about
„ III.—2·75 „ „ „ } 7 per cent.

The increased loss in III. is probably due to moisture, as it had not been bottled, but merely wrapped in paper.

But that the loss in the other cases is not due to moisture, several things show—firstly, the sublimate being weighed nearly equals the loss, and the acidity loses in proportion to the loss instead of increasing as it would have done otherwise.

To the acidity I shall refer later on, as also to the nature of the sublimate. The samples were now ignited: one of them (I.) being first heated on a sand bath, a microscope slide received an amorphous sublimate from 130—140°, another slide from 145—150° received a copious sublimate of acicular crystals and amorphous matter, and these crystals also collected on top of the new brownish mass of saccharine (several measuring from 6 to 7mm. in length). At 160—170°. appearance was dark-brownish in colour; 180—190° it fused; and subsequently melted to a clear yellow liquid which boiled very soon afterwards.[‡‡]

It was then heated gently and ignited over the open flame. While heating in the sand bath it gave off a very sweet vapour which could be tasted several feet away.

The ash, after complete ignition, weighed:—

I.—1·63 per cent. } Average of two results.
II.—5·68 „ „ }
III.—Not enough of sample for ignition.

This residue is also noticed further on.

The Sublimate at 100° C. These crystals correspond exactly in appearance and grouping with those obtained by cooling a hot aqueous or alcoholic solution of saccharine.

I have reproduced a rough sketch of some of these. Fig. 1, Nos. I. and IV. show sublimate as on watch-glass—I. being near edge of glass and IV. in the centre. No. III. shows crystals from aqueous solution; the crystals will be noticed as invariably in tufts. Benzoic acid from aqueous solution is shown in II. for comparison.

The crystals have a sweet taste, and seem indubitably saccharine itself. This loss is important in affecting estimations of moisture if done in the ordinary way.

The residue after ignition consists of sodium salts, mainly sulphate, the ash from II. showing 5·05 per

FIG. 2.

Sublimate at 100° C.

(Magnified 200 Diameters.)

cent. Na_2SO_4 when estimated with barium chloride; and comes, I suppose, from sodium ortho-toluene-sulphamido-benzoate which has not been completely separated from the saccharine.

Nevertheless this would seem to be a somewhat important point for wholesale buyers. As to the presence of iron in ash as noted in the journal referred to, there was no trace shown in any of my samples when tested with freshly prepared $K_4Fe(CN)_6$ or KCNS.

The acidity was estimated with 1grm., decinormal Na_2CO_3 and NH_4HO being used with litmus and phenolphthalein as indicators.

I. required 17·0cc. = 87·11 per cent. of saccharine,
II. " 18·1cc. 88·02 " "

The ash of II. taken as sulphate and calculated to sodium salt of saccharine makes up nearly the difference.

But there is a discrepancy in No. I. probably due to presence of the ammonium salt from Fahlberg's sulpho-benzoic acid recovery process.

Tests.—The crystalline sublimate, together with the sweet fumes, etc., given off on heating, are characteristic.

Fusion with caustic alkali yields salicylic acid.

Potassium ferro and ferric cyanides give greenish coloured precipitates on boiling—the latter, as already noted, being so delicate a test, that a 1 in 1000 solution gives a very characteristic apple-green colour. These precipitates are soluble in caustic alkali and reprecipitated on addition of acid.

I have to apologise for these somewhat incomplete notes. I should like to have given complete analyses as well as to have noted other points, but these, I trust, will be given by someone who has more opportunity and time to devote to the subject.

In reply to a question of the Chairman, Mr. SUTHERLAND said: The solubility in water is—in cold water (15·5° C.), barely 0·1 per cent.; in boiling water fully 1 per cent. A 1 in 1000 solution, however, has a very sweet taste, and even a 1 in 10,000 solution has a perceptibly sweet taste.

◆◆◆

NOTES ON THE ANALYSIS OF SOME MINERAL OIL GASES.

BY JAS. B. MACARTHUR.

THE destructive distillation of mineral oils for the production of illuminating gas is a process which this Society is already so well acquainted with, that any detailed account of it is quite superfluous on the present occasion.

The various forms of apparatus now in use give substantially the same results, and are worked at such a heat as will give a yield of from 85 to 100 cubic feet of 50 to 60 candle gas from each gallon of oil used, equal to 22,000 or 28,000 cubic feet of gas per ton of oil.

The oil used may be Burning Oil of 0·80 to 0·81 sp. gr., or the cheaper Intermediate Oil of 0·84 to 0·87 sp. gr.

It is well known that these mineral oils consist of a complex mixture of hydrocarbons, principally members of the olefine and normal paraffin series. In passing through a red-hot retort (the most suitable temperature for which seems to be about 800—1000° Centigrade), the oil readily breaks up into gas, the illuminating principles of which have been shown by the exhaustive researches of Armstrong and Miller to consist principally of members of the olefine, benzene, and pseudo-acetylene series, with mere traces of true paraffins or other saturated hydrocarbons.

This almost complete absence of the higher paraffins from ordinary high-heat oil gas led me to inquire whether an oil gas produced at a lower temperature would also be destitute of paraffins among its illuminating constituents, and more especially, whether paraffins would be found in the gas which is produced during the distillations, with open steam, to which mineral oil is subjected in the ordinary course of refining.

In these distillations, as has already been communicated to this Society, there is always produced a considerable amount of permanent gas—frequently as much as 1 cubic foot per gallon of crude oil distilled.

With crude shale oil, or, as in the case of the gases which have here been examined, in the first distillation of once-treated shale oil, the gas begins to be evolved when about two-thirds of the oil charged into the still have been distilled over.

At successive stages of the distillation, it is found to vary considerably in illuminating power and in composition. The first portion of gas formed is the product of the decomposition of the oil at the lowest possible temperature under the conditions, and, as will be seen from the following results of its analysis, is very rich in heavy hydrocarbons. As the distillation progresses, and the temperature of the still rises, the gas becomes poorer, less luminous, and contains hydrocarbons of a lower carbon density, until at the end of the distillation, when only spongy "coke" remains in the still, the luminosity of the gas which continues to come off is reduced to 10 or 15 candles, and the total carbon density of the gas to little over unity.

The gas as sampled at the end of the condensing worm was in all cases saturated with naphthas of low boiling point, which are also the decomposition products of the heavy oil.

In all cases the samples for analysis were collected over water, and were left for some time at a temperature of 50—55° F. to deposit any condensed naphtha.

For the sake of comparison, analyses were also made of ordinary high temperature oil gas produced from intermediate oil of 0·86 sp. gr. in a small iron retort. In the case of Nos. 6 and 7, as reported below, the temperature of the retort was purposely raised much beyond that usually employed for oil gas making, so much so in fact that the iron retort was quickly burned out.

The gas apparatus at my disposal for these analyses was of somewhat primitive form, and unavoidable errors may have crept in; but the fair agreement of the amount of oxygen consumed and contraction in volume after explosion, with what is demanded by theory for olefines and paraffins of the carbon density found, shows that these errors have not vitiated the results to any serious extent.

Great difficulty was experienced in finding a suitable absorbent for members of the paraffin series which could be applied after the removal of the olefines, etc., by bromine. It was necessary to effect their absorption in order to determine the vapour density of these heavy paraffins, to examine the residual gas, and especially to test for free hydrogen. Alcohol was deemed unsuitable owing to the difficulty experienced in removing its vapour from the scrubbed gas, and recourse was made to mineral oil of about 0·87 sp. gr., which had previously been deprived of its dissolved air by heating and steaming. This was still a somewhat imperfect absorbent, and its action on the lower members of the paraffin series was feeble. Marsh gas, as made from acetate of soda and slaked lime, and purified by caustic soda and bromine, was found to be absorbed to a considerable extent, but it was difficult to ensure its complete absorption. No attempt was made in the ordinary analyses to absorb this first member of the series, and to avoid doing so a uniform treatment of five volumes of oil per 100 of gas was adopted, though this probably left some of the next higher member, ethane, also unabsorbed. Treatment with a larger proportion of oil would have complicated the results by dissolving a considerable amount of the marsh gas, and by reducing the carbon density of the absorbed paraffins to such an extent that no true indication of the illuminating paraffins present in the gas would be obtained.

The candle power stated is only approximate, and the sp. gr. of the gases was roughly estimated by observing the rate of diffusion of the samples through a minute orifice, and comparing it with that of air under the same conditions.

The results are as follow :—

LOW TEMPERATURE GAS FROM STILLS.

	No. 1.	No. 2.	No. 3.	No. 4.
Sample taken at—	Beginning of Gas Production.	Middle of Gas Production.	Near Coking Stage.	Fully Coked.
Sp. gr. of gas, air = 1·00	1·10	1·05	0·67	—
Luminosity in candles	30, 35	30, 35	25, 30	10, 15
Vols. CO_2 after combustion per 100 of gas	229·0	215·1	134·2	101·1
Bromine absorption ..	20·0	18·0%	8·0%	3·5%
Carbon density of olefines	4·24	4·05	3·51	—
Oil absorption of residue per 100 of original gas	—	19·4	9·0	—
Carbon density of absorbed paraffins	—	4·30	3·00	—

Vols. CO_2 on combustion per 100 of residue from oil absorption	83·2	60·2	56·0

The low carbon densities of the high temperature gases, Nos. 5, 6, and 7, especially after removing the heavy hydrocarbons, show the presence of free hydrogen. This gas occurs almost of necessity, from the decomposition of the paraffins into the less highly hydrogenated olefines, and from the formation of coke. At lower temperatures, these high-boiling paraffins break up into lower olefines and paraffins, which latter may be largely represented in the case of this still gas by CH_4. Sample No. 7 of high heat gas was repeatedly scrubbed with oil after the removal of the olefines in the usual way, when 100 vols. of the residue gave only 32 vols. of CO_2, the hydrogen being 131·1, which agrees well with a mixture of two volumes of hydrogen and one volume of marsh gas

In the low temperature gas from stills, the presence of free hydrogen was also proved. In sample No. 2, the brominated gas was thoroughly scrubbed with oil, the combined absorption being 71 per cent. One hundred volumes of this residue gave 68 volumes of CO_2, while the oxygen consumed and contraction on exploding agreed well with that required by theory for a mixture of two volumes of marsh gas and one volume of hydrogen. This result (which was confirmed by duplicate trials) would show the presence of about 9 per cent. of free hydrogen in the original gas.

It is hardly possible that this free hydrogen found in the gas from oil stills could be derived from the decomposition of the steam used in the distillation, as the temperature of the still was much too low. When this sample of gas was taken, there was a considerable residue of oil in the still, the bottom being completely covered, as fresh oil had been fed in during the distillation. And if any decomposition of the steam had taken place, any hydrogen thus formed would have been accompanied by an equal volume of carbonic oxide, and this gas, as well as carbonic acid, could not be detected. The free hydrogen had probably been produced from the semi-coked sediment at the bottom of the still, which was nearly red hot when the sample was taken.

In an analysis of similar samples of gas, which was made by Prof. Forster, of London, and communicated to the Gas Institute in June, 1887, free hydrogen was considered to be absent. But in the analysis he quotes, only the olefines were removed, none of the paraffins being absorbed, and the carbon density of the residual gas was 1·31, the hydrogen being 4·62. Though this residue has the composition of pure paraffins, as stated, the same figures would be obtained from a mixture of :

20 vols. propane,
71 vols. marsh gas, and
9 vols. hydrogen,

or even from a mixture of :

65·5 vols. ethane and
34·5 vols. hydrogen,

or from any of a great number of mixtures containing free hydrogen. The carbon density of the residual gas not having been reduced below unity, free hydrogen was not proved to be absent.

The great richness in heavy carbon compounds of this gas produced in oil-refining stills, makes it very remarkable, but, at the same time, its luminosity is disappointing. Thus, sample No. 3 of low-heat, and No. 5 of high-heat gas, have both a carbon density of 1·3, but while the latter is of 50, 60 candle-power, the low-heat still gas is only 30 to 35 candles. A comparison of Nos. 4 and 6 is still more striking, the luminosity of the high-heat gas being always much higher than that of the low-heat gas from stills, the carbon densities being equal. But similar differences in luminosity may be found in comparing marsh gas with a carbon density of 1·0, which has only 5 candle-power, with coal gas, which, with an average carbon density of 0·40, may be of 25 to 30 candle-power. Also, it is stated by Berthelot that hydrogen mixed with 3 per cent. by volume of benzol vapour burns with about 20 candle-power, although it has a carbon density of only 0·09.

The heavy hydrocarbons present in still gas seem to consist of olefines and paraffins, or bodies similar to these, in about equal proportions, and thus it differs altogether from ordinary oil gas, which has practically no heavy hydrocarbons which are not removed by bromine. Thorpe and Young found solid paraffin wax to break up into liquid paraffins and olefines, in about equal proportions, when distilled repeatedly under pressure at comparatively low temperatures : and ordinary shale gasoline, which is the most volatile part of the naphtha recovered by scrubbing the retort gas with oil, was proved to be of similar composition. Its vapour was mixed with air, and the mixture analysed in the usual way. The sample tested was saturated at about 40° F., and burned with about 25 candle-power. The total hydrocarbons present were found to amount to 35·8 per cent. by volume, with an average carbon density of 5·4. The bromine absorption was 18·7 per cent. with a carbon density of 5·5, and the oil absorption of the residual gas amounted to 17·1 per cent. on the original, with a carbon density of 5·3. This shows that the gasoline, as vapourised, contained 52·2 per cent. of vapour of olefines, which is equal to about 52·7 per cent. by weight.

No examination has yet been made of the naphtha which always accompanies the gas from oil stills. This will partly pass away in the gas, even with very thorough condensing power : but towards the end of the distillation, the condenser requires to be kept somewhat warm to prevent choking of the pipes with solid paraffin, and, in consequence, very little of this naphtha arising from the decomposition of the heavy oils, is recovered, and a very considerable loss thus occurs. The quantity of this naphtha is now proportionately less than it was some years ago, as the tendency in oil-refining now is to have as little destruction of the oil in the course of the distillation as possible, and to rely more on chemicals for its purification. But it is impossible to avoid all decomposition in the still, and, in consequence, a quantity of naphtha which—whatever may be its exact chemical composition—is of low boiling point, and therefore of considerable value, is every day being lost in our mineral oil refineries.

Journal and Patent[*] Literature.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

Improvements in Filter-presses. D. K. Clark, London. Eng. Pat. 11,589, Sept. 11, 1886. 11d.

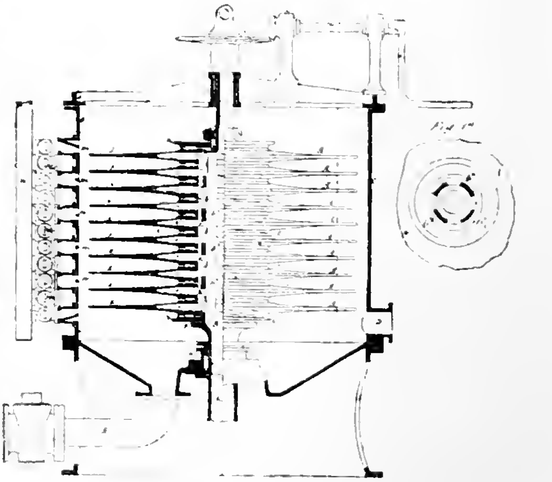
THE diaphragm or body of the filter-press plate, which the patentee has hitherto made in a separate piece from the rim, is in the present instance cast therewith in one. The drainage grooves are made in a radial direction from centre to circumference and these empty into one or more concentric grooves, which, in their turn, communicate with a number of outlet ones, disposed radially and passing through the body of the rim of the plate.
—C. C. H.

Improvements in Filters for Domestic Purposes. C. A. Clapham, Bradford. Eng. Pat. 9527, July 23, 1886. 8d.

THE improved filter consists of a cylindrical vessel, with a contracted orifice at the lower end screwed to receive pipe and covered with a perforated plate. The upper part is precisely similar to the lower part, except that it is screwed on to the body of the filter, thereby compressing the granular carbon between the two perforated plates. Such a filter can be attached to a water tap.—C. C. H.

Improvements in Filters. J. E. Hodgkin and E. Perrett, London. Eng. Pat. 15,158, Nov. 22, 1886. 11d.

THIS class of filter is more particularly intended for removing the solid matter precipitated from a hard water in the process of softening. The figure annexed shows one modification. In the vessel C mounted on a hollow spindle B are a number of corrugated hollow discs A, somewhat resembling the grooved plates of a circular filter-press. The discs are covered with cloths. The turbid water enters the tank at D, filters through the cloth into the corrugations on each plate, into the hollow interior a, and away through b^2 into the hollow spindle B, and thence conducted away by pipe b. The solid matter accumulated on the clothed discs is removed by rotating the whole series by means of the mechanism shown so as to enable jets of water m to play on the surface and wash away the deposit, which escapes through the pipe H. The specification shows two other modifications, in which the hollow spindle B is mounted horizontally.—C. C. H.



Composition for Removing Scale or other Incrustations from the Inside or other Parts of Steam Boilers. J. Brookbanks, North Shields. Eng. Pat. 12,498, Oct. 2, 1886. 4d.

THE composition consists of one part of sulphate of soda, one part of nitre cake and one part of alkali.
—C. C. H.

Improvements in Filter-presses. E. A. Cowper, London. Eng. Pat. 14,415 Nov. 8, 1886. 1s. 1d.

THE improvements described in this specification consist in (1) providing an arrangement of links, chains or ropes, so connecting the chambers that when the follower is withdrawn by means of an endless chain, mechanically worked, the whole chambers are simultaneously opened ; (2) opening or closing the chambers one at a time by means of a sliding friction pawl carried by reciprocating bars ; (3) effecting the tightening of the press by means of the pressure in the interior of the machine, itself acting upon an hydraulic ram forming part of, but larger in diameter than, the head of the machine; (4) expediting

---

[*] Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows :—

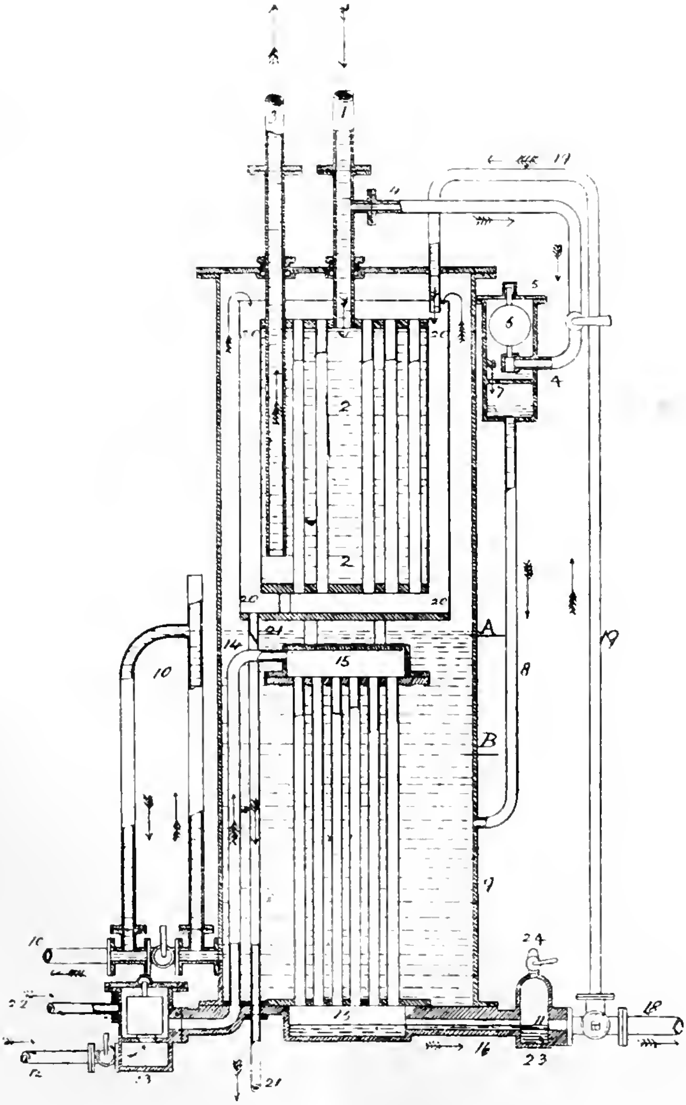
If the price does not exceed 8d.........	½d.
Above 8d., and not exceeding 1s. 6d...	1d.
,, 1s. 6d., ,, ,, 2s. 4d...	1½d.
,, 2s. 4d., ,, ,, 3s. 4d...	2d.

filtration by intermittently injecting air under pressure along with the material undergoing filtration; (5) assisting the removal of the cake from the faces of the chambers by means of springs or projections on the said faces, or by forcing air or water under pressure behind the filtering cloth before the machine is opened.

—C. C. H.

Improvements in Machinery for Producing Distilled Water from Sea or other Impure Water. A. L. Normandy, London. Eng. Pat. 12,419, Sept. 30, 1886. 8d.

THE accompanying figure shows the construction of the improved apparatus. The vessel 9 contains the two tubular vessels, 2 and 15, the lower of which is immersed in impure water undergoing distillation. Steam is supplied from a boiler through pipe 12 and steam reducing valve 13 into 15, where it condenses, passing away through steam trap 23, either by pipe 18 or by pipe 19 into vessel 20, where it mixes with the "secondary condensed water" in the upper vessel. Cold water is supplied through pipe 1 to the upper condenser, and condenses the steam arising from the condensing water in the lower part of the apparatus; this mixes in 20 with that from 15 and is carried by pipe 21 to any desired point. The condensing water in 2 passes away through pipe 3. A portion of the water entering pipe 1 is led through 4, through the float box 6 and by pipe 8 enters the lower point of 9, where, as has been described, it is both distilled and acts as a condensing agent. The concentrated brine passes away through pipe 10. Excess pressure in vessel 9 lowers the water level as from A to B, and thus reduces the evaporative power.—C. C. H.



Improvements in Filter-presses. J. Critchlow, T. Forester, W. Forester, H. Forester, and L. Forester, Longton. Eng. Pat. 2915, Feb. 25, 1887. 8d.

THE filtering cloths are replaced by porous tiles resting and bedded on the drainage faces of the chambers of the filter-press. The tiles or porous composition consist of charcoal, blue clay, ball clay, China clay, flint and stone mixed together with water, formed into cakes and fired.

—C. C. H.

Improvements in and relating to Filtering Apparatus. C. J. Bühring, Hamburg, Germany. Eng. Pat. 3848, March 14, 1887. 8d.

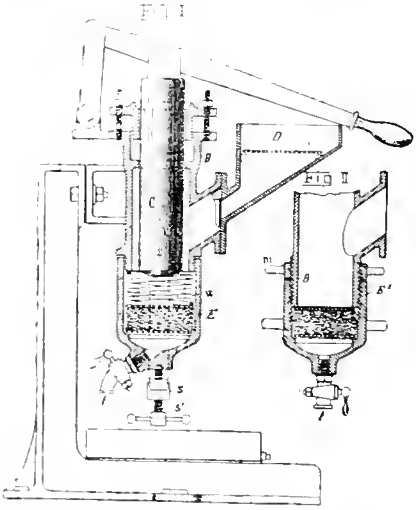
THE new filter is made of enamelled wrought iron and resembles in shape an inverted bottle. The inlet is at the top or large end, which is closed by a loose cover secured by a clip, and the outlet is at the lower and smaller end. The filtering medium consists of a hollow block of carbon, covered with an iron bell perforated at the lower end and surrounded with granulated charcoal. Above this, again, is an asbestos plate, holding coarsely granulated charcoal surmounted by a charcoal plate to break the force of the water. The filter as arranged is directly connected with the water main. Sometimes it is used in conjunction with a pump, in which case a three-way cock is used, so that either filtered or unfiltered water can be drawn as desired.—C. C. H.

Improved Method of and Apparatus for Preventing Corrosion in Steam Boilers. E. M. B. Faull and F. W. Cannon, London. Nov. 22, 1886. 4d.

THE feed water is passed through an iron vessel, in the bottom of which is a zinc plate covered by a perforated iron plate: suspended vertically in the vessel are three plates, two of iron, one of zinc; the zinc plate is connected with the exterior of the boiler by a copper wire, and a return circuit from the outside of boiler to the iron plates. The combination forms "a battery of sufficiently destructive power to destroy any galvanism contained by the feed water."—C. C. H.

An Improved Filtering and Lixiviating Press. C. A. Koellner, Kiel, Prussia. Eng. Pat. 7515, May 25, 1887. 8d.

THE accompanying Figs. show the improved filtering press. B is a force pump, with plunger C fed from hopper D, provided with inlet valve. Below this, and secured thereto by bolts, a screw thread or a stirrup and screw is the filtering chamber E or E^1 in which is compressed by the spring W, or its equivalent in screws, the filtering bed. Reciprocation of the pump plunger forces the liquid through the filtering medium and out by the cock t. The solid matter is left in the filtering chamber, and can be lixiviated in a similar manner.—C. C. H.

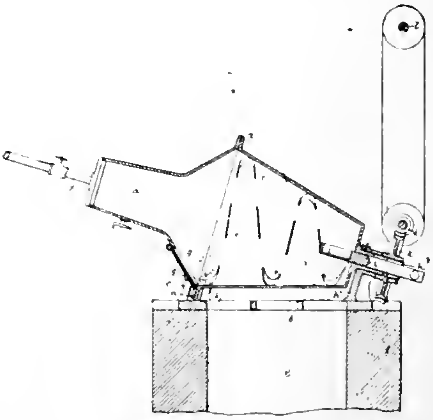


Improvements in Apparatus for Separating by Subsidence Solid Matters from the Liquids in which they are Suspended. W. Macnab, sen., W. Macnab, jun., Forest Gate, and J. Donald, Paisley. Eng. Pat. 7830, May 28, 1887. 8d.

A HORIZONTAL tank is divided into two parts; the first part communicates with the second through holes cut in the separating diaphragm. The first portion of the tank is again divided by vertical partitions, so that any liquid entering the apparatus passes first to the bottom, rising and descending once again before entering the second part of the apparatus. This ensures the thorough admixture of any reagents. In this part a series of sloping shelves are placed alternately reaching to the top and bottom, the distance between them increasing. The spaces between these are filled with sloping shelves parallel to the partitions, the distance between these being greater in the end nearest the entrance to the tank, and *vice-versâ*. A turbid liquid entering the apparatus deposits its solid matter on these subsidence shelves and following an up-and-down course finally becomes quite clarified. The mud slides down the shelves into the lower part of the tank and is removed through cocks.—C. C. H.

Improvements in Apparatus for Calcining, Drying, Roasting or Carbonising Substances or Materials and Extracting Gases, Spirits or Acids therefrom. R. Cunliffe, Pendleton, and J. Lund, St. Annes-on-the-Sea. Eng. Pat. 10723, Aug. 4, 1887.

THE improved apparatus consists of a bottle-shaped vessel a, runnning on friction rollers c c, and a hollow trunnion bearing h, contained by a base plate b and suspended over a furnace c. The neck is fitted with a pipe f for the conveyance of the gases, etc. evolved during distillation to any desired point. A door g serves for the introduction of the material and blades e for its agitation during rotation. Spirits or volatile oils may be introduced through the plug i i^1. The whole is rotated by the worm k^1 and worm wheel k.—C. C. H.



Improvements in the Construction of Filters. R. Clayton, Deepfields. Eng. Pat. 11,035, Aug. 12, 1887. 6d.

THE improved filter consists of a vessel, cylindrical or otherwise, in the interior of which is suspended a second vessel of similar shape, the lower part of which carries the filtering body. This consists of layers of sand, fine and granulated charcoal enclosed between two carbon plates or asbestos cloths.—C. C. H.

II.—FUEL, GAS AND LIGHT.

Improvements in the Use and Construction of what are known as Mantles for Incandescent Gas Lighting. A. Paget, Loughborough. Eng. Pat. 16,581, Dec. 17, 1886. 8d.

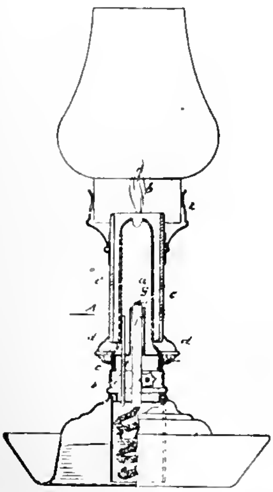
INSTEAD of being suspended by the top, the mantle is supported at the bottom by resting on a ring, collar or shelf round the top of the burner. It may be fastened to this support with shellac, glass or other suitable cement. To prevent side motion, a wire is carried upward from the burner and bent down so as to enter the aperture at the top of the mantle and hold it in position; or this wire may be carried upwards inside the mantle, and answer the same purpose. The mantle may be strengthened by making it of a fabric increasing in thickness or closeness from the top to the bottom and, to ensure an easy fit over the burner or collar without undue slackness, a wire inserted in a "welt" or "slack course" provided for it in the bottom of the mantle. For strengthening purposes, this wire may also be inserted at the top of the mantle.—A. R. D.

Improved Blowpipe Apparatus for Producing Intense Heat and Artificial Light. S. Pitt, Sutton. From J. R. Knapp, New Orleans, U.S.A. Eng. Pat. 9077, June 25, 1887. 11d.

This is an apparatus in which nitrous oxide is used to support the combustion of a jet of hydrogen. The nitrous oxide in liquid form is stored in a cylinder, which forms part of the apparatus. For details of construction, the specification with its explanatory drawings must be consulted.—A. R. D.

Improvements in Apparatus for Burning Heavy Mineral and Other Oils. L. Chandor, St. Petersburg, Russia. Eng. Pat. 12,336, Sept. 12, 1887. 6d.

These improvements relate to the so-called "Tischolin candlestick," described in Eng. Pat. 10,234, Aug. 23, 1885. They consist—Firstly, in the substitution of a metallic, ground or milk glass or porcelain cylinder *c* for the tightly-fitting mantle, which heretofore was placed over the perforated metal cylinder with inner gauze lining. This outer cylinder is not provided with airholes at the top, but stands in a circular cap *d* with airholes *e*. The air entering by these holes is thus warmed as it passes to the upper flame *b*. Secondly, in surrounding the wick tube *f* with another tube *g*. The space between these tubes communicates by the openings *h* with the outside air and thus provides for the combustion of the lower flame *a*. Thirdly, in the use of the small tube *i* which reaches down into the oil reservoir and leads any gases formed there up to the lower flame to be consumed.—A. R. D.



III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Improvements in the Method of and in Apparatus for the Utilisation of Gas Tar. G. Hammond, Lewes. Eng. Pat. 14,395, Nov. 8, 1886. 1s. 1d.

It is proposed to continuously and automatically distil coal tar by means of high-pressure steam in order to recover the illuminating hydrocarbon vapours and convey them to the gas mains for the purpose of enriching and increasing the volume of coal gas in course of manufacture, the residual tar being also used as fuel in the retort furnace or other fires. The specification contains five sheets of drawings.—D. B.

Improvements in Carbonising or Distilling Coal or Shale. J. Young, Stoke-on-Trent. Eng. Pat. 14,840, Nov. 16, 1886. 4d.

By adding sodium chloride to the coal, the coke produced is said to be improved in quality, whilst the resulting gas can be more easily purified. The quantities of illuminating gas and ammoniacal compounds produced are also said to be increased. The quantity of salt to be used depends on the composition of the coal, but in most cases 4lb. of salt to 1 ton of coal will be found to give the desired result.—D. B.

IV.—COLOURING MATTERS AND DYES.

Azo-Colouring Matters from the Paradiamines of Stilbene and Fluorene and their Sulphonic Acids. Dingl. Polyt. J. **265**, 478—479.

As is known, the azo-colouring matters, which are obtained by the combination of *para*-tetrazo-compounds with naphthylaminesulphonic acids, naphtholsulphonic acids or phenolcarboxylic acids, possess the property of dyeing unmordanted cotton and have become during the past few years dangerous rivals to the natural colouring matters.

For their preparation, the *para*-diamines of diphenyl, ditolyl and dixylyl and the derivatives of these bases have been principally employed. Recently, the firm of A. Leonhardt & Co. have proposed *diamidostilbene*, *diamidofluorene* and their sulphonic acids, as the starting-point in the preparation of these azo-dyes.

Diamidostilbene is prepared from *p*-nitrobenzylchloride. This is treated with an alcoholic solution of potash, and the *p*-dinitrostilbene thus obtained reduced with tin and hydrochloric acid, yielding diamidostilbene, a substance which crystallises in needles or plates and melts at 226—227°.

The base is more easily obtained when paranitrotoluene is digested with alcoholic soda. A complicated product is obtained, which, by treatment with tin and hydrochloric acid, is converted into diamidostilbene.

On a large scale, the base is obtained by boiling for a long time 50kilos. of *para*-nitrotoluene with 100 litres of alcohol and 30kilos. of soda solution of 40° B. The spirit is distilled off and the unchanged *para*-nitrotoluene removed in a current of steam. The product remaining behind is suspended in 10 parts of alcohol and heated under an inverted condenser for a long time with 5 parts of concentrated hydrochloric acid and 1 part of tin chloride. After distilling off the spirit, the tin is precipitated by zinc and the new base separated from the concentrated liquid with excess of soda. It is then purified by means of the sparingly soluble hydrochloride.

In order to obtain diamidostilbenesulphonic acid, 50kilos. of sodium *p*-nitrotoluene sulphonate are dissolved in hot water and gradually decomposed with 100kilos. of soda solution of 40° B. This is then diluted with 500kilos. of water and 50kilos. of zinc dust are added little by little. When the solution becomes colourless, it is filtered hot and the *diamidostilbenesulphonic acid* separated by hydrochloric acid as a yellow, sparingly-soluble powder.

Diamidofluorene is prepared by Schultz's method: by the fractional distillation and crystallisation of the portion of coal tar boiling between 290—330°, the fluorene is separated from the other hydrocarbons in this fraction. By treating this with strong nitric acid and reducing the resulting nitro-compound, *diamidofluorene* is obtained; this, with concentrated sulphuric acid, yields *diamidofluorenesulphonic acid.*

From these amido-bodies and their sulphonic acids, the azo-dyes can be obtained by combination with amines, phenols, or their sulphonic or carboxylic acids. The tetrazo-compound, formed by acting on the base or its sulphonic acid with nitrous acid, combines first with one molecule of the respective amine or phenol, forming an intermediate product, which then acts on a second molecule. This property has been employed in order to obtain the so-called mixed azo-dyes, by combining two different amine or phenol molecules with one molecule of a tetrazo-compound.

The following colouring matters were obtained in the above-mentioned manner:—

Dye from diamidostilbene and α-naphtholmonosulphonic acid.—28·3kilos. of diamido-stilbene hydrochloride are dissolved in 5000 litres of water. 24kilos. of hydrochloric acid of 20° B. added, and converted into the tetrazo-compound by the addition of a solution of 13·8kilos. of sodium nitrite in 200 litres of water. This latter is then allowed to act, with frequent shaking, on an alkaline solution of 49·2kilos. of sodium α-naphtholmonosulphonate in 5000 litres of water. After standing some days, the mixture is heated to boiling, the colouring matter salted out, pressed and dried. It dyes cotton a bluish-violet without mordant.

Dye from diamidostilbene and β-naphtholdisulphonic acid.—When the α-naphtholmonosulphonic acid above mentioned is replaced with 69·6kilos. of β-naphtholdisulphonic acid, a colouring matter is obtained which dyes cotton in an alkaline soap-bath greenish-blue. When 1mol. of diamidostilbene is combined with 1mol. of β-naphtholdisulphonic acid and 1mol. of α-naphtholdisulphonic acid, a colouring matter is obtained which, in regard to tint and solubility, falls between the two previous ones.

By further combination of diamidostilbene with α-naphthol, β-naphthol, or β-naphtholmonosulphonic acid, colouring matters are obtained which dye cotton in an alkaline bath, blue to bluish-violet.

A yellow dye is obtained from diamidostilbene and salicylic acid.

From *diamidostilbenesulphonic acid*, other dyes can be obtained in a similar manner; and diamidofluorene also yields technically useful colouring matters with *α-naphthylaminesulphonic acid* or *β-naphtholdisulphonic acid*.

—G. H. M.

On Sulphon-Fluorescein Ira Remsen and C. Hayes. Amer. Chem. J. **9**, 372—379.

By heating *ortho*-sulphobenzoic acid with resorcinol to 178—185° for about seven hours, the liquid which has at first a clear deep-red colour, begins to thicken and yellow, crystalline plates appear, when the whole soon turns to a thick, nearly solid yellow paste. The mass is extracted with water and the sulphon-fluorescein separated from the aqueous solution by concentrations and re-crystallisation. It forms straw-coloured crystals, ready soluble in water. The aqueous solution is slightly fluorescent, the alkaline solution more so, but nothing like that of fluorescein. Heated to 250° it does not melt, but is decomposed at 300°, forming in part a dark brown flocculent mass insoluble in water and soluble in alkalis, yielding a strongly fluorescent solution. Its composition appears to be analogous to that of fluoresceïn, the CO group being replaced by SO_2. Its crystals contain two molecules of water of crystallisation. An aqueous solution of sulphon-fluorescein decomposes carbonates with the formation of salts. The barium salt forms straw-coloured crystals, the exact composition of which is at present undecided. When sulphon-fluoresceïn is treated with excess of bromine in acetic acid solution, a crystalline dibromide is probably formed. The strongly alkaline solution of sulphon-fluoresceïn becomes colourless when treated with zinc dust, probably forming a substance analogous to fluoresceïn, which owing to its extreme solubility could not be isolated. The decolorised solution is readily coloured again by oxidising agents or by simply allowing it to stand exposed to the air.

—C. A. K.

The Coal-tar Colours and the Revision of the Laws concerning Injurious and Non-injurious Colouring Matters. P. Cazeneuve. Ann. d'Hygiéne, 1887, **18**, 1.

The following colours are considered as non-injurious by the author:—(1) Soluble red (roccellin); (2) the sodium salt of the sulphonic acid of rosaniline; (3) purple red (obtained by the action of the diazo-compound of alpha-naphthylamine mono-sulphonic acid on beta-naphthol alpha disulphonic acid); (4) Bordeaux red B, formed from the diazo-compound of alpha-naphthylamine and beta-naphthol-alpha-disulphonic acid; (5) Ponceau R (from diazo-xylidine and naphthol-beta-disulphonic acid); (6) Orange I (from the diazo-compound of sulphanilic acid and alpha-naphthol); (7) Yellow N S (sodium salt of dinitronaphtholsulphonic acid); (8) Soluble yellow (sodium salt of amido-azo-*ortho*-toluenesulphonic acid); (9) Ordinary Indulin (the sodium salt of the sulphonic acid obtained from the product of the action of amido-azobenzene on aniline); (10) Coupier's blue (sodium salt of a sulphonic acid derivative of violaniline); (11) Acid green (sodium salt of the mono-sulphonic acid of malachite green). The sodium salts of sulphonic acids are not poisonous as a rule, while nitro-compounds (*e.g.*, dinitronaphthol) are poisonous. Methylene blue is injurious. The author proposes regulations in regard to the sale and use of artificial colouring matters in colouring food—viz., that the colours must be free from sodium sulphate and other impurities, whether injurious or not: neither wine, vinegar, beer nor butter should be artificially coloured: and that the manufacturer should be held responsible for the quality and nature of his products.—C. A. K.

Derivatives of Triphenylmethane. C. Ullmann. J. Prakt. Chem. **36**, 246—272.

By the action of benzaldehyde upon mixtures of aromatic amines with their hydrochlorides, diamido-derivatives of triphenylmethane are obtained. Benzaldehyde-aniline and aniline-hydrochloride at 110—120° give rise to the already known *diamidotriphenylmethane*. This body is also formed by heating benzylidine-aniline with aniline hydrochloride. By heating benzaldehyde with *o*-toluidine and its hydrochloride, *diamidodi-o-tolylphenylmethane* $C_6H_5.CH[C_6H_3(CH_3)NH_2.]_2$ [1 : 3 : 4] is produced, though it does not appear to have been obtained in a pure state. On oxidation it gives a bluish-violet colouring matter. By a similar reaction, *p*-toluidine gives rise to *diamidodi-p-tolylphenylmethane* $C_6H_5.CH[C_6H_3(CH_3)NH_2]_2$ [1 : 3 : 6, though the yield is much smaller than in the preceding cases. This compound crystallises from benzene, with ½mol. of C_6H_6, in small, colourless prisms; from alcohol it crystallises in needles. It melts at 185—186° and distils with slight decomposition at about 27—33°. It scarcely has any tendency to form a dyestuff on oxidation. By diazotising and treatment with hydriodic acid it is converted into *di-iododi-p-tolylphenylmethane* $C_6H_5.CH[C_6H_3I(CH_3)]_2$, which crystallises from alcohol in prisms of melting-point 167—168°. When diamidodi-*p*-tolylphenylmethane is distilled with zinc dust it is resolved into *p*-toluidine and methyl-acridine 
$\left\langle \begin{matrix} CH \\ | \\ N \end{matrix} \right\rangle C_6H_3(CH_3)$, the latter of which forms small felted needles, of melting-point 131·5°.

The di-acetyl derivative of diamidodi-*p*-tolylphenylmethane $C_6H_5.CH[C_6H_3(CH_3)NH.C_2H_3O]_2$ crystallises from alcohol in colourless prisms on plates and melts at 217—218°.

The *di-benzoyl derivative* $C_6H_5.CH[C_6H_3(CH_3)NH.CO.C_6H_5]_2$ forms small prisms, which melt at 196°.

—A. G. G.

Cotton Colouring Matters. E. Erdmann. Chem. Ind. **10**, 427—433.

Until quite recently, the only dyestuffs known which had any natural affinity for cotton were a few non-nitrogenous plant-colouring matters (bixin, carthamin, curcumin, etc.) and the strongly basic compounds saffranine and methylene blue. Since 1885 an entirely new class of azo-colouring matters have been introduced which have a very marked affinity for the cotton fibre, which they dye from a neutral or slightly alkaline bath without a mordant. The first cotton colours discovered were all derivatives of benzidine and tolidine, and upon this fact R. Möhlan (*Ber.* 19, 2014) has based a theory that the affinity of these colours for cellulose is a function of the diphenyl group. More recently, however, a variety of other cotton colours have been discovered which do not possess this grouping, so that upon what peculiarity of the molecular structure the affinity for cotton depends still remains undetermined. Amongst the cotton colours which are not derivatives of diphenyl are those derived from diamidostilbene $C_6H_4(NH_2).CH:CH.C_6H_4(NH_2)$ and its sulphonic acids. This base is obtained by reduction of *p*-nitrobenzyl-chloride, or by the action of caustic alkalis and zinc-dust upon *p*-nitrotoluene (Bender and Schultz, *Ber.* 19, 3234; Walter, *Bull. Soc. Ind. de Mulhouse*, 1887, 99). According to a recent patent of the Badische Fabrik (Germ. Pat. 39,955), cotton colours are obtained from the naphthylene-diamine, formed by reduction of alpha-dinitronaphthalene. Further, di-*p*-amido-azobenzene $C_6H_4(NH_2).N:N.C_6H_4(NH_2)$ and *p*-phenylene-diamine also give rise to azo-colouring matters with an affinity for cotton, though those derived from the latter base do not find technical employment on account of their sensitiveness to light. On the other hand, the azo-colouring matters derived from di-*p*-amido-benzophenone $C_6H_4(NH_2).CO.C_6H_4(NH_2)$ and from di-*p*-amidodiphenylmethane $C_6H_4(NH_2).CH_2C_6H_4(NH_2)$ have scarcely any affinity for cotton. Whilst it is the diazotised base which appears to determine the affinity for the fibre of the resulting azo-compound, the shade produced is almost entirely dependent upon the phenol or amine with which the diazo-compound is combined. Thus, with the above-mentioned bases, phenol, phenol-sulphonic acid and salicylic acid give yellows; alpha-and beta-naphthylamine and their sulphonic acids give reds; and alpha-and beta-naphthols and their sulphonic acids give violet to blue shades. The compounds obtained from alpha-naphthylaminesulphonic acid are stronger colours than those from the sulphonic acids of beta-naphthylamine; but the former are more sensitive to acids, which change their colour to blue, whilst the latter are changed to brown. Instead of combining the diazotised diamido base with 2mols. of one phenol or amine, compounds of a mixed type may be obtained by first uniting one N_2 group with 1mol. of a phenol or amine and then uniting the second N_2 group with 1mol. of a different phenol or amine. This is readily done, as the combination of the second N_2 group takes place much more slowly than that of the first. The compounds $R'.N_2.X.N_2.R''$ prepared in this way dye shades intermediate between the colours $R'.N_2.X.N_2.R'$ and $R''.N_2.X.N_2.R''$ obtained by combining the diazotised diamine with two similar mols. of each phenol or amine separately. Thus:—

Congo Corinth B, the colour from

$$\text{Tolidine}\begin{cases}\text{Alpha-naphthionic acid}\\ \text{Alpha-naphtholsulphonic acid}\end{cases}$$

is intermediate in shade between *Benzopurpurin* 4 B:

$$\text{Tolidine}\begin{cases}\text{Alpha-naphthionic acid}\\ \text{Alpha-naphthionic acid}\end{cases}$$

and *azo-blue*:

$$\text{Tolidine}\begin{cases}\text{Alpha-naphtholsulphonic acid}\\ \text{Alpha-naphtholsulphonic acid.}\end{cases}$$

A.—BENZIDINE COLOURS.

1. *Congo red:*

$$\text{Benzidine}\begin{cases}\text{Alpha-naphthylaminesulphonic acid}\\ \text{Alpha-naphthylaminesulphonic acid.}\end{cases}$$

(Actien Gesellschaft für Aniline Fabrication, Germ. Pat. 1884, 28,753). This was the first cotton azo-colour, and was discovered by Böttiger. Cotton yarn is dyed from a bath containing 3 per cent. of borax, 5 per cent. of salt and 4 per cent. of green soap. For printing, a solution of

300grms. of Congo Red,
100 ,, ,, caustic soda liquor (36° Bé.),
in 1500 ,, ,, water,

is added to a mixture of

1000 grms. of gum tragacanth,
1200 ,, ,, flour,
300 ,, ,, white soap,

and boiled. Congo red is very sensitive to acids, by which it is turned blue. Its aqueous solution gives a blue precipitate on the addition of a trace of any acid, on which account it is employed as an indicator in alkalimetry.

2. *Chrysamine:*

$$\text{Benzidine}\begin{cases}\text{Salicylic acid}\\ \text{Salicylic acid}\end{cases}$$

(Fr. Bayer & Co., Germ. Pat. 1884, 31,658).

This yellow colouring matter is very sparingly soluble in water, but dissolves more readily in a solution of soap. Aqueous caustic soda dissolves it very easily, forming a red solution of the basic salt. Cotton yarn is dyed from a bath containing 1 per cent. of chrysamine, 10 per cent. of phosphate of soda, and 2½ per cent. of soda. For printing, the following mixture is employed:—

1500grms. of water.
1200 ,, ,, flour.
1000 ,, ,, gum tragacanth.
300 ,, ,, white soap.
300 ,, ,, chrysamine.

Chrysamine is extraordinarily sensitive to traces of iron and copper salts, which change its colour to brown. Knecht has found that chrysamine acts as a mordant towards basic aniline colours.

3. *Azo-orseilline:*

$$\text{Benzidine}\begin{cases}\text{Alpha-naphtholsulphonic acid}\\ \text{Alpha-naphtholsulphonic acid}\end{cases}$$

dyes wool an archil shade. Dissolves in conc. H_2SO_4 with a blue colour, which becomes violet on addition of water.

4. *Benzidine-blue:*

$$\text{Benzidine}\begin{cases}\text{Beta-naphtholdisulphonic acid R}\\ \text{Beta-naphtholdisulphonic acid R}\end{cases}$$

(G. Schultz, *Ber.* 17, 462) has no technical value.

5. *Deltapurpurine:*

$$\text{Benzidine}\begin{cases}\text{Beta-naphthylamine-}\ \delta\ \text{-sulphonic acid}\\ \text{Beta-naphthylamine-}\ \delta\ \text{-sulphonic acid}\end{cases}$$

(Fr. Bayer and C. Duisberg, *Ber.* 19, 1426).

6. *Yellow-paste:*

$$\text{Benzidine}\begin{cases}\text{Sulphanilic acid}\\ \text{Phenol}\end{cases}$$

dyes cotton from a hot bath a greenish yellow, but is a weaker colour than chrysamine. It dissolves in conc. H_2SO_4 with a reddish-yellow colour.

6. *Congo G R:*

$$\text{Benzidine}\begin{cases}\text{Alpha-naphthionic acid}\\ m\text{-sulphanilic acid}\end{cases}$$

dyes cotton a yellowish scarlet.

8. *Congo Corinth:*

$$\text{Benzidine}\begin{cases}\text{Alpha-naphthylaminesulphonic acid}\\ \text{Alpha-naphtholsulphonic acid}\end{cases}$$

dyes a Corinthian red.

9. *Brilliant-congo G:*

$$\text{Benzidine}\begin{cases}\text{Beta-naphthylaminedisulphhonic acid}\\ \text{Beta-naphthylaminemonosulphonic acid}\\ \text{(Brönner's)}\end{cases}$$

is dyed best with the addition of potash. It is stable towards dilute acetic acid.

B.—TOLIDINE COLOURS.

1. *Benzopurpurine B:*

$$\text{Tolidine}\begin{cases}\text{Beta-naphthylaminesulphonic acid.}\\ \text{Beta-naphthylaminesulphonic acid.}\end{cases}$$

This red-colouring-matter was the first tolidine derivative that came into the market. It dyes from a bath containing 10 per cent. of potash or phosphate of sodium.

2. *Benzopurpurine 4 B:*

$$\text{Tolidine}\begin{cases}\text{Alpha-naphthylaminesulphonic acid.}\\ \text{Alpha-naphthylaminesulphonic acid.}\end{cases}$$

(Germ. Pat. 35,615.)

Its shade is almost the same as that of Congo red, and, like the latter, it is changed by acetic acid.

3. *Deltapurpurine 7 B.*

$$\text{Tolidine}\begin{cases}\text{Beta-naphthylamine-}\delta\text{-sulphonic acid.}\\ \text{Beta-naphthylamine-}\delta\text{-sulphonic acid.}\end{cases}$$

(Fr. Baeyer & C. Duisberg, *Ber.* **19**, 1426.)

4. *Azo-blue:*

$$\text{Tolidine}\begin{cases}\text{Alpha-naphtholsulphonic acid.}\\ \text{Alpha-naphtholsulphonic acid.}\end{cases}$$

(Fr. Bayer & Co., Germ. Pat. 1885, 35,341.)

This dyestuff forms a dark-coloured powder, which dissolves in water with a bluish-violet colour, changed to red by alkalis, but unaffected by acids. Conc. H_2SO_4 dissolves it with a pure blue colour. Cotton is dyed from a bath containing soap and 10 per cent of sodium phosphate of soda (also in some cases sulphate of soda). It gives dull reddish-blue shades.

5. *Rosazurine G and B* (Fr. Baeyer & Co.) are prepared from tolidine and alkylated beta-naphthylaminesulphonic acids.

6. *Congo Corinth B:*

$$\text{Tolidine}\begin{cases}\text{Alpha-naphthionic acid}\\ \text{Alpha-naphtholsulphonic acid}\end{cases}$$

dyes a bluer shade than the corresponding benzidine colour.

7 *Congo 4 R:*

$$\text{Tolidine}\begin{cases}\text{Alpha-naphthylaminesulphonic acid}\\ \text{Resorcinol}\end{cases}$$

dyes very beautiful shades, but is even more sensitive to acids than Congo, being slowly decomposed even by carbonic acid.

8. *Brilliant Congo R:*

$$\text{Tolidine}\begin{cases}\text{Beta-naphthylaminedisulphonic acid}\\ \text{Beta-naphthylaminemonosulphonic acid}\\ \text{(Brönner's)}\end{cases}$$

(Actiengesellschaft, Germ. Pat. 41,095.)

dyes cotton slowly; the colour is stable towards dilute acetic acid.

C.—DIANISIDINE COLOURS.

Benzoazurine:

$$\text{Dianisidine}\begin{cases}\text{Alpha-naphtholsulphonic acid}\\ \text{Alpha-naphtholsulphonic acid}\end{cases}$$

is the bluest azo-colour yet brought into the market. Cotton is dyed an indigo-blue shade with 5 per cent. of colour.

D.—DIAMIDOSTILBENE COLOURS (A. Leonardt & Co.)

1. *Hessian Purple N:*

$$\text{Diamidostilbenedisulphonic acid}\begin{cases}\text{Beta-naphthylamine.}\\ \text{Beta-naphthylamine.}\end{cases}$$

2. *Hessian Purple B P* and *D* are derived from diamidostilbenedisulphonic acid and the various naphthylaminesulphonic acids.

3. *Hessian Yellow:*

$$\text{Diamidostilbenedisulphonic acid}\begin{cases}\text{Salicylic acid}\\ \text{Salicylic acid}\end{cases}$$

dyes a redder shade than chrysamine.

4. *Brilliant Yellow:*

$$\text{Diamidostilbenedisulphonic acid}\begin{cases}\text{Phenol.}\\ \text{Phenol.}\end{cases}$$

Very similar in shade to Hessian yellow. Alkalis change its colour to red, forming basic salts.

5. *Chrysophenine* is an alkyl derivative of the preceding compound. It is unaffected by alkalis.

—A. G. G.

Chromogenic Properties and Preparation of the Oxyanthraquinones. C. Liebermann and S. v. Kostanecki. Annalen, **240**, 256—304.

THE authors, by a method which they call the "rufi-reaction," and which consists in condensing two molecules of benzoic acid or its substitution products by means of concentrated H_2SO_4, have succeeded in preparing a number of anthraquinone derivatives. They find that of the oxybenzoic acids, the meta-oxy-compounds most readily undergo condensation and this they ascribe to the greater stability of the acid towards the concentrated H_2SO_4 and at high temperatures. Of the compounds prepared in this way the following may be mentioned:—

Meta-oxybenzoic acid condenses with benzoic acid to form oxyanthraquinone, according to the following equation:—

$$C_6H_5CO_2H + C_6H_4(OH)CO_2H = 2H_2O + C_{14}H_8O_3$$

At the same time oxybenzoic acid condenses with itself, so that a number of isomeric dioxyanthraquinones are formed—viz., anthrarufin, erythroxyanthraquinone, anthraflavinic acid and *m*-benzdioxyanthraquinone, which may be separated by means of the different solubilities of the barium salts or of the acetyl derivatives. The latter method is used in the separation of monoxy- from benzdioxyanthraquinone.

Benzoic acid condenses also with symmetrical dioxybenzoic acid to form xanthopurpurin and anthrachryson. The former is separated from the latter by its solubility in benzene, or by that of its barium compound in water.

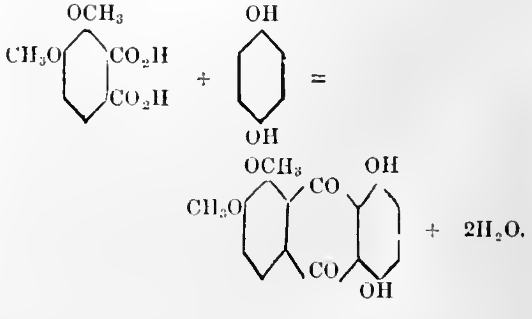
By heating *m*-oxybenzoic acid and gallic acid with concentrated H_2SO_4 to 150°, a variety of condensation products are formed. Of these rufigallic acid is the chief product and in smaller quantities two isomeric tetraoxyanthraquinones. The two latter may be separated by their different solubilities in benzene. The condensation of symmetrical dioxybenzoic acid and gallic acid yields a pentoxyanthraquinone, together with by-products formed by condensation of each acid with itself. By a method analogous to the above, the authors have prepared a series of homologues of the oxyanthraquinones by means of the homologous oxy-acids. Thus, for example, *m*-oxytoluylic acid and oxybenzoic acid yield dimethylanthrarufin $C_{14}H_4(CH_3)_2O_2(OH)_2$ and dimethylanthraflavinic acid isomeric with the former. In addition to these two a third isomeric dimethyl-*meta*-benzdioxyanthraquinone occurs in the product in small quantity. In the same way dimethylanthrachryson and methylanthragallol have been prepared from cresorsellinic and *o*-toluylic acids, and the latter also by condensation of gallic acid and toluylic acid, in which case four isomeric methylanthragallols are formed. Dimethylanthragallol is prepared from xylylic acid—

$$C_6H_3(CH_3)_2CO_2H\ [CH_3 : CH_3 : CO_2H = 1 : 3 : 4]$$

and gallic acid, and trimethylanthragallol from durylic acid and gallic acid.

The authors find that the solution of the oxyanthraquinones in concentrated H_2SO_4 give (absorption) spectra which are characteristic of the different isomeric bodies. Also the methyl homologues indicate by this means the oxyanthraquinone from which they are derived, giving almost identical spectra with the oxyanthraquinone. In this way they have been able to determine the constitution of chrysophanic acid, which is a derivative of chrysazin.

Hemipinic acid condenses with quinol (hydroquinone) to form the dimethyl ether of quinalizarin, according to the equation:—



On heating this compound with HCl, quinalizarin is obtained, which, according to its mode of formation, is a tetrahydroxyanthraquinone.

Similarly hemipinic acid combines with cresol to form the dimethylether of methylhydroxyalizarin.
—J. B. C.

VI.—DYEING, CALICO PRINTING. PAPER STAINING AND BLEACHING.

Improvements in the Mode of Producing Certain Colours on Cotton, Linen and other Textile Fabrics. L. Hamel, Manchester. Eng. Pat. 1775, June 22, 1870 (Second edition). 6d.

To reduce the cost of indigo dyeing, the cloth is first padded in a solution containing per gallon from 1 to 16ozs. of aniline salt and from one-eighth of an ounce to 4ozs. of chlorate of potash, according to the weight of the cloth and the depth of the shade required. After drying, the usual resist indigo colours (preferably with addition of a little resin paste) are printed on and the pieces are aged for two or more days at a temperature of about 80° F. The cloth is then dyed in indigo in the proportion of from 2 drachms to 2ozs. of indigo to the pound of cloth, according to the quality of the indigo, the pattern and the depth of shade required. In this way patterns in white, blue, green, orange, yellow, red and black on a blue ground are produced much cheaper than heretofore. (The use of chlorate of potash as described in the final, is not stated in the provisional specification.)—W. E. K.

Improvements in Dyeing and Printing Aniline Black. T. Holliday, Huddersfield. From W. J. S. Grawitz, Paris, France. Eng. Pat. 3073, August 3, 1878 (Second edition). 6d.

The invention relates to the development of aniline black on textile fibres by the action of chromic acid on a mixture of a chlorate and a salt of aniline; small quantities of chromic acid, one part to 10,000, or even 100,000 parts by weight of the aniline mixture being sufficient, larger quantities acting with increased rapidity. To prevent the black forming in the vessels in which the mixture is contained, the mixture of chlorate of potash and aniline salt may be rendered alkaline, preferably by ammonia, and the salt of chromic acid added at the time of use. For a printing colour

1000	parts of	water,
200	„	starch.
80	„	chlorate of potash,
130	„	hydrochloride of aniline,

are mixed and heated to 90° C., and when cold one-tenth of a part of chromate of potash or ammonia is added. After printing the goods are aged by warm damp air, by steaming or other suitable means. For dyeing purposes the larger portion or the whole of the starch is omitted. The process may be modified by applying to the fibre first the chromic acid or its salts and afterwards the mixture of chlorate and aniline salts. Any chromate can be used from which during the operation chromic acid is set free. The claim is "the improvements in dyeing and printing textile fibres aniline black by the action thereon of chromic acid in the presence of chloric or perchloric acid on aniline substantially as described."—W. E. K.

Improvements in Dyeing Fabrics and in Materials and Apparatus therefor. E. Boursier, Brussels, Belgium. Eng. Pat. 7740, May 27, 1887. 8d.

This invention relates (*a*) to the composition of the dye-bath and (*b*) to the arrangement of the apparatus used. It is specially applicable to the dyeing of silks, ribbons and velvets, preserving the fineness, suppleness and brilliancy of the fabrics, not only with new goods, but also in the case of old stocks that require to be re-dyed. The dye-bath, which is used cold, consists of oil of naphtha (petroleum naphtha), "benzine" or other hydrocarburetted liquid, to 100 parts of which are added 12 parts of a mordant containing 59·3 per cent. of margaric, oleic or stearic acid, 27·1 per cent. of pure alcohol and 13·6 per cent. of "volatile alkali." As tinctorial material, alcoholic solutions of the aniline colours are employed, with an addition of 5—10 per cent. of the above oil mordant. From 1—6 per cent. of this alcoholic solution is added to the hydrocarburet bath, according to the shade required. The dye vessel is cylindrical in shape and has a central shaft to which are attached movable discs, which can be fixed at any desired point on the shaft by means of screws. These discs carry arms radially arranged in the form of a regular polygon of which the shaft is a centre and provided throughout their length with small hooks on to which the fabric is hooked by its selvidge spirally around the shaft. With narrow ribbons it is necessary to fix one selvidge only, with wider goods the fabric is fixed by both selvidges to a pair of discs. The dye vessel has a close fitting cover, through which the upper end of the shaft passes and by means of a crank the goods are rotated within the dye vessel until the dyeing is completed. After dyeing, the shaft and the goods it carries is transferred to a second similar vessel, but with open ends, and is rotated at a speed of from 700 to 1200 revolutions per minute by a band and pulley attachment. The goods thus dried are subjected to a "fixing" operation, "essence of naphtha" alone or with a little acetic acid being used. After again drying as before, the goods are ready for the usual finishing processes.—W. E. K.

Improvements in Dyeing Yarn and other Fibrous Materials, and in Means or Apparatus employed therein. T. Sampson and F. H. Jealous, Lawrence, U.S.A. Eng. Pat. 12,358, Sept. 13, 1887. 8d.

The apparatus consists of an arrangement by which the yarn is dyed in stationary receptacles or dye vessels, through which the dyeing liquors are caused to circulate. For convenience of handling, the yarn is carried in bags, which are lowered into the cylindrically-shaped dye-vessels, and suitable flanged covers are provided, which so press upon the bags as to cause the liquors to pass uniformly through the whole mass of yarn. Three or more of these dye vessels are fixed in a vat, being sustained above the bottom of the vat by a partition plate, which also divides the vat into an upper and a lower chamber. There are openings at the bottom of the dye vessels and also in their covers, so that the communication between the upper and lower chambers of the vat is through the interior of the dye vessels themselves. The dye liquor is placed first in the upper chamber, from this pumped into the lower chamber and being forced through the interior of the dye vessels comes again into the upper chamber, this circulation of the dye liquor being continued until the dyeing process is completed. The lower chamber is supplied with upright stand pipes, through which the dye liquor passes and is conveyed to the upper chamber whenever the pressure in the lower compartment exceeds a certain maximum limit. At the bottom of the vat is a pipe, by means of which the dye liquor can be run off into a closed tank when the operation is over and through which also the dye can again be forced up into the vat when dyeing a fresh supply of yarn.—W. E. K.

VII.—ACIDS, ALKALIS AND SALTS.

Action of Sulphurous Acid on Nitrous Acid. F. Raschig. Annalen, **241**, 161—252.

The following series of salts have been prepared by Fremy and were subsequently studied by Claus. These have been further re-investigated by the author and a different formula assigned to them. If neutral solutions of KNO_2 and K_2SO_3 be mixed, crystals separate out which have the formula $N(SO_3K)_3 + 2H_2O$. This nitrilosulphonate of potassium on boiling decomposes, yielding potassium amidosulphonate NH_2SO_3K. If the nitrilosulphonate moistened with dilute H_2SO_4, be exposed for a day, washed with cold water and crystallised from dilute ammonia solution, the imidosulphonate is formed, $NH(SO_3K)_2$. The author has not isolated a corresponding sodium compound, for, on account of its ready solubility, it does not crystallise from solution; but if to the solution KCl solution be added a salt of the formula $N(SO_3K)_2.SO_3Na$ separates. Potassium hydroxylamine disulphonate is prepared by first obtaining the sodium compound and then adding KCl solution to this. Sodium nitrite, finely powdered, is dissolved in the least possible quantity of water, ice added, and sodium bisulphite solution in the proportion of two molecules to one of the nitrite allowed to run in and stirred, potassium chloride is added and the whole allowed to crystallise. It may be recrystallised from (a slightly alkaline) solution in hot water. The compound decomposes on standing into hydroxylamine monosulphonic acid, $HO.NH.SO_3H$, and potassium sulphate. This compound decomposes on boiling with water for some time, or more quickly in slightly (HCl) acid solution in sealed tubes, at 130°, into hydroxylamine. The disulphonate may be completely converted into hydroxylamine sulphate by boiling the strong aqueous solution with water, according to the equation $2HON(SO_3K)_2 + 4H_2O = (NH_3OH)_2SO_4 + 2K_2SO_4 + H_2SO_4$. Free hydroxylamine may also be obtained by adding to an acidified solution of the disulphonate an excess of alkali. In titrating an acid solution of hydroxylamine with permanganate, the author finds that more permanganate is used than corresponds to the oxidation to N_2O, according the equation $2HONH_2 + 2O = N_2O + 3H_2O$. This is due probably to the formation of hyponitrous acid, which splits up into N_2O and H_2O on the one hand, and is oxidised further to nitrous and nitric acid on the other. If the titration is done with hydroxylamine sulphate in the boiling solution, the reaction is very definite, and the amount of O required corresponds to the formation of NO. The titration may also be accomplished with ferric sulphate, which is deoxidised by the hydroxylamine. The amount of ferrous salt is then determined By acting upon a strongly alkaline solution of KNO_2 with SO_2 a compound of the formula—

$$\begin{matrix} KO \\ HO \end{matrix}\!>NSO_3K$$

is obtained. If excess of alkali be added to this salt, potassium sulphite is formed. Potassium sulphazinate is formed by adding to a cooled alkaline solution of KNO_2 a solution of $KHSO_3$. This compound has the formula $KHN_2O_2(SO_3K)_2$. It decomposes on standing into hydroxylamine sulphonate of potassium and KNO_2. The author explains the formation of these compounds by the supposition that condensation occurs between potassium bisulphite with the unsymmetrical formula $H.SO_2.OK$ and nitrous acid, thus:—

$$(HO)_3 : N + H.SO_2.OK = (HO)_2 : N.SO_2.OK + H_2O.$$
$$(HO)_2 : N.SO_2.OK + H.SO_2.OK = HO.N : (SO_2.OK)_2 + H_2O$$
$$HO.N : (SO_2OK)_2 + H.SO_2.OK = N : (SO_2OK)_3 + H_2O.$$

Sulphazotinate of potassium is obtained in crystals by passing SO_2 into a strongly alkaline KNO_2 solution. It has the formula $K_5HN_2S_4O_{14} + H_2O$. It dissolves in strong potash solution, and on addition of alcohol a crystalline powder separates, having the formula $K_6N_2S_4O_{14} + H_2O$. This the author names basic potassium sulphazotinate. The faintly acid solution of the neutral salt yields on boiling aqueous hydroxylamine-sulphonate of potassium $KHN_2O_2(SO_3K)_4 + 2H_2O = 2HONHSO_3K + K_2SO_4 + KHSO_4$. With CO_2 a different reaction occurs, $KHN_2O_2(SO_3K)_4 + H_2O + CO_2 = 2HON(SO_3K)_2 + KHCO_3$. To sulphazotinic acid, the author, from the method of synthesis, gives the following formula:—

$$(SO_3K)_2 : NH\!<\!\begin{matrix} O \\ O \end{matrix}\!>\!NK(SO_3K)_2.$$

—J. B. C.

Improvements in the Manufacture of Fluoride of Aluminium and the Double Fluoride of Aluminium and an Alkali. L. Grabau, Hanover, Germany. Eng. Pat. 13.654, Oct. 25, 1886. 6d.

THIS invention relates to the preparation of fluorides and fluorine double compounds by the action of suitable quantities of an alkaline fluoride on a peculiar solution prepared from aluminium sulphate or alum. A solution of either of the latter two salts is mixed with pulverised fluor-spar and heated; the greater part of the alumina combines with fluorine, while gypsum is simultaneously formed. The remaining sulphuric acid is, however, no longer present as aluminium sulphate or alum, but in chemical combination with the aluminium fluoride, so that the solution can be designated an "aluminium fluorine sulphate solution." This is the peculiar solution mentioned previously. If this solution be mixed with as much of an alkaline fluoride as is equivalent to the sulphuric acid combined with alumina and lime, the mixture evaporated, heated and lixiviated with water, the residue consists of aluminium fluoride. To prepare the double fluorides, "aluminium fluorine sulphate solution" is mixed with as much fluoride of sodium or potassium as is necessary for converting all the aluminium into the double fluoride and the small quantity of dissolved gypsum into calcium fluoride. The whole mixture is then evaporated to dryness.—S. H.

Improvements in the Distillation of Ammoniacal and other Liquors, the Concentration of Liquids and Salts in Solutions, and in the Means or Apparatus employed therein. S. H. Croll, London. Eng. Pat. 15,391, Nov. 25, 1886. 8d.

IN concentrating ammoniacal or other liquors, the solutions flow into a series of superposed receiving vessels contained in a vertical still. The lowest receiver is provided with suitable means of drawing off its contents. Underneath the still a fireplace for smokeless fuel is arranged, the combustion gases of which are made to pass over the surface of the liquors. In the case of a liquid requiring its vapour to be treated for partial or complete absorption, the gases and vapours are drawn into a chamber or second vessel, where they are treated with the suitable reagent or passed through absorbent matter. If noxious gases are given off by the liquor, they may be burned in the fireplace. In other cases they may be sent directly into the chimney. If it be desired to force the vapours from the liquors below the surface of an absorbing agent in another chamber, an exhauster must be used.—S. H.

Improvements in Treating Solutions of Chloride of Calcium, so as to obtain Chloride of Magnesium and other Products. W. P. Cochrane and W. Bramley, Middlesbrough. Eng. Pat. 15,498, Nov. 27, 1886. 6d.

HYDRATED MAGNESIUM CARBONATE is charged into a series of closed vessels, whilst a solution of calcium chloride is run through the vessels, passing from one to the other, carbonic acid being at the same time injected into the mixture. Magnesium chloride is gradually formed in solution and calcium carbonate precipitated. The solution of magnesium chloride is treated for the manufacture of hydrochloric acid, chlorine and magnesia therefrom, while the precipitated calcium carbonate may be utilised for the decomposition of ammonium chloride. The hydrated magnesium carbonate requisite for this process is obtained by treating sodium bicarbonate with magnesia (Eng. Pat. 13,762, 1886).—S. H.

Improvements in the Manufacture of Sulphate of Soda and Bleach in one Operation under High Pressure, and in the Construction and Use of Apparatus for that Purpose. H. Burns, Leith. Eng. Pat. 15,488, Nov. 27, 1887. 8d.

SULPHUR or pyrites are burnt in a close blast retort, and the sulphurous acid given off led into a condenser and then into a closed vessel containing cold water, which absorbs the sulphurous acid. This solution is run into a close boiler and heated up to the boiling point, whereby all the sulphurous acid is again liberated. It is mixed with an additional amount of air and forced through sodium chloride contained in a retort and kept at a high temperature. The salt is decomposed, giving off hydrochloric acid which is led into a mixing condenser, to be mingled with double its quantity of air, the mixed gases being forced through a second decomposing

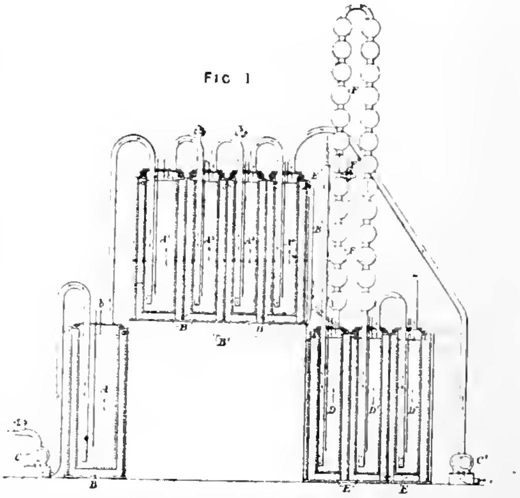
retort, filled with the peroxide of iron or manganese, and kept at a red heat. In passing through the oxide, the hydrochloric acid is decomposed into steam and chlorine. The escaping gases are cooled to condense the steam and, after washing, are dried by being forced through sulphuric acid. The dry chlorine is then led into a lime chamber, which is filled with a movable perforated floor and gas-tight doors. The perforated floor is covered with lime and the gas enters the chamber under the false floor and being forced through the lime is quickly absorbed. It is claimed that the sodium sulphate produced by this method is of superior quality, while the bleaching powder can be made stronger and at less cost than by any other process. Fig. 1 shows a vertical sectional elevation of a works for the manufacture of sodium sulphate and bleach at one operation. A is a vertical iron cylinder lined with fire bricks, having a boiler B set on the top of it. A is charged with pyrites through the central tube C, and a blast of air blown in through the pipe F G. The sulphurous acid passes up C and enters at the top of the condenser D and forces its way down into the bottom of the washing vessel H. The gas then enters the condenser I and passes by the pipe J into the bottom of the absorber K; in bubbling up through the water in K the greater portion of the gas is absorbed, while the remainder passes into a second absorber M, fitted with a cup and ball agitator, where the last traces of sulphurous acid are retained. The nitrogen and excess of air escape by the valve V and enter the annular space N; being here relieved of pressure, the gases rapidly expand, thereby keeping M cool. They then pass through the condensers by pipes n and escape into the air. The water charged with sulphurous acid enters the boiler at Q; here it is heated by the heat of the burning pyrites and gives off its sulphurous acid. The hot water overflows at R, while the gas passes by the pipe T into the annular space U, formed by the concentric iron cylinders W. In the centre of the latter a tapering pipe X is fixed, perforated with a number of small holes. The interior cylinder W is also perforated with small holes, through which the gas passes from the annular space U. These combined cylinders are set in a furnace, the fire gases of which surround the cylinders. The annular space W is filled with salt, and a blast of air being turned into S here mixes with steam and sulphurous acid from B. The mixture of the gases and vapours passes through into U, then by the perforations in the cylinder through the salt, which is rapidly decomposed. The hydrochloric acid gas escapes into the perforated tube X and thence into the condenser Z by the pipe Y. Through the pipe P air is forced into Z and the mixed gases pass by pipe a into the decomposing retort b, which is made of iron, with a perforated pipe r fitted into the bottom. Here the decomposition of the hydrochloric acid takes place and, after the escaping gases have been cooled, washed and dried by sulphuric acid, the chlorine is forced into the bleaching-powder chamber f.—S. H.

Improved Treatment of Hydrochloric Acid Gas for the Production of Chlorine Gas. W. Donald, Pembrey. Eng. Pat. 62, Jan. 3, 1887. 8d.

THE object of this invention is to obtain chlorine from hydrochloric acid and to recover the by-products formed during the process. Hydrochloric acid gas, dried by passing through a vessel charged with concentrated sulphuric acid, is passed into a vessel containing a mixture of strong nitric and sulphuric acids, where it undergoes decomposition according to the following equation: $2HCl + 2NO_3H = 2H_2O + N_2O_4 + Cl_2$. The sulphuric acid present absorbs the water formed by the reaction and thus prevents an unnecessary dilution of the nitric acid. The decomposing vessel ought to be kept at a temperature of 0° C., while the escaping gases should not be warmer than 30° C. These latter then travel through a series of vessels containing dilute nitric acid, whereby nearly the whole of the oxides of nitrogen become absorbed, while the last remaining traces are arrested by passing through a sulphuric acid scrubber. The apparatus employed is shown in Figs. 1 and 2. A, A^1, A^2, A^3, A^4 are a series of closed cylindrical stoneware vessels, each resting in a separate tank, through which a continuous flow of refrigerated brine is kept up. The gaseous hydrochloric acid is forced by means of a blower C into the drying vessel A. The dried gas then passes into the decomposer A^1, thence in succession through the absorbers A^2, A^3 and A^4, from which it is drawn off by a second blower C^1. D, D^1 and D^2 are vessels of similar construction as A and serve for converting the lower oxides of nitrogen collected in A^2 and A^3 into nitric acid. Each vessel rests in a separate tank E. The vessel D is heated by hot water from the outside, whereas D and D^2 are cooled by refrigerated brine. The liquor from A^2 and A^3 is run into D, where it is heated while a slow current of air is passed through, the lower oxides of nitrogen being thus oxidised into nitric acid. From D the air passes through a tower F, carrying with it free oxides of nitrogen which during their progress undergo further oxidation, the necessary water being supplied to the tower. The condensed gases flow back into D, while those uncondensed pass into D , which is charged with nitric acid, and are ultimately scrubbed in D^2 with sulphuric acid. The oxidation of the gases is also assisted by compounds rich in oxygen, such as manganese peroxide, manganese nitrate, and so forth. The recovered acids are again used for the process.—S. H.

FIG 1



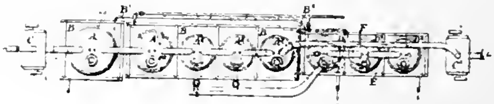


FIG 2

Improvements in the Production of Sulphide of Zinc and Chloride of Ammonium. H. Kenyon, Manchester. Eng. Pat. 16,118, Dec. 9, 1886. 6d.

IN the galvanising of iron, zinc waste is obtained containing zinc, iron, lead, manganese, chlorine and ammonia. It is dissolved in hydrochloric acid and the lead precipitated from the solution by the addition of sulphuric acid. The precipitate is filtered and the filtrate treated with ammonia, agitating well in order to oxidise iron and manganese. Sulphuretted hydrogen is then passed into the clear solution, until all the zinc is precipitated as sulphide, while the ammonia is converted into ammonium sulphide. The former is separated by filtration and the solution of ammonium sulphide treated with an equivalent quantity of zinc chloride, to obtain a precipitate of zinc sulphide and ammonium chloride.
—S. H.

X.—METALLURGY, Etc.

Composition of the Refined Lead from Przibram. Dingl. Polyt. J. **264**, 463.

The analyses of the refined lead from Przibram for the successive quarters of the year 1886 gave the following results:—

—G. H. M.

Improvements in Extracting Gold, Silver and other Metals from Ores or Compounds containing the Same. A. Parkes, London. Eng. Pat. 13,073, Oct. 13, 1886. 6d.

The crushed ore is mixed in a reverberatory furnace with caustic lime and soda, the approximate proportion by weight of three parts of caustic lime to one part of caustic soda, and with carbonaceous matter; if reducible compounds of lead or copper are not present in the ore they should also be added. On fusion a metallic bath, containing practically the whole of the precious metals, will be produced, from which the latter may be subsequently recovered. Sulphur ores should not be roasted first; they may be worked as above or may be made to give an auriferous and argentiferous regulus which may then be treated; the use of the soda-lime flux is found to cause a rapid disintegration of the regulus, especially if it be sprinkled when hot with cold water. The peculiarities of any given ore may require a modification of the fluxes; thus, the addition of oxide of iron, barium carbonate, fluor spar or cryolite may frequently be desirable. A cupola may sometimes be substituted for the reverberatory furnace, in which case the ore will not be fine-crushed.—W. G. M.

Improvements in the Humid Reduction of Gold and other Ores. J. E. Baugh and C. Hinksman, London. Eng. Pat. 13,928, Oct. 30, 1886. 6d.

If the ore should be free from copper a small proportion of copper pyrites should be mixed with it. Otherwise, or after this addition, it is chlorinated in the furnace described in Eng. Pat. 11,766 of 1886. A chemical test is then made to prove the complete solubility of the gold, so that a further chlorination with free chlorine may, if necessary, remedy any defect in this respect. The charge is then leached with boiling brine, and the gold, silver and copper in the solution are precipitated simultaneously by means of iron or zinc. A more complete extraction of the precious metal than by previous processes is thus effected, especially in the case of low grade or pyritous ores. The chlorine is preferably to be obtained by treating chloride of lime with sulphuric or sulphurous acid, these substances, if desirable, being by-products of the process.

—W. G. M.

An Improved Method of Smelting and Recovering Metals from Ores and Dross. J. Nicholas, Ilford. Eng. Pat. 14,297, Nov. 5, 1886. 8d.

The matter to be treated may contain either gold, silver or tin; it is first heated, preferably to a red heat in a reverberatory furnace, and immediately plunged into a cold saturated or very strong solution of any alkali or chloride. It is thus disintegrated, may be fine-crushed with ease and the chemical effect will render the subsequent reduction more satisfactory. When dealing with tin compounds a furnace of special construction is recommended. It is so arranged that by the regulation of dampers the flame from the grate either plays over the bed as in an ordinary reverberatory, or is diverted into a flue beneath the bed as in a kind of muffle furnace. Thus, the access of oxygen to the charge is under perfect control.—W. G. M.

Improvements in Machinery for Coating Metallic Sheets or Plates with other Metals or Alloys. H. A. Stuart, Bletchley, and C. R. Binney, London. Eng. Pat. 15,320, Nov. 24, 1886. 8d.

This patent relates to tin and terne plating. The grease pot is arranged to give the smallest possible contact with the tin bath and is surrounded by a hot-air chamber, by which the temperature is kept under control. By an arrangement of conical rollers each plate on entering the bath is delivered at an angle with that last introduced, and driven forward within guides, which are adjustable for various sizes of plate, and thence through scrapers having a lateral motion to the finishing rolls. The motion is transmitted to the rolls by worm gearing, which imparts a more even rotation and gives, therefore, a more perfect surface on the plate than was possible with spur gearing.—W. G. M.

Improvements in the Process of Obtaining Alloys of Aluminium with certain other Metals. J. Clark, Birmingham. Eng. Pat. 15,946, Dec. 6, 1886. 6d.

Hydrated aluminium chloride is mixed with lime, iron, zinc, ammonia, or other substance which readily combines with chlorine, and with finely divided coke. After drying, this mixture is to be introduced into the (iron) blast-furnace, added to the cementation charge or blown through the metal in the Bessemer converter, with the object of producing an alloy of iron and aluminium, or of aluminium with spiegeleisen or other iron alloys.—W. G. M.

Improvements in and in Apparatus for Cleaning or Pickling Metals and in Utilising the Liquids that have been employed therefor. E. Vlasto, Paris, France. Eng. Pat. 16,923, Dec. 24, 1886. 8d.

All the operations of pickling and washing are conducted in the same vessel. A series of reservoirs is arranged, one containing the acid, the others the different wash waters. A pipe from each reservoir runs over the pickling tub and supplies the required liquid through a branch provided with a cock. After sufficient time has elapsed, the liquid is raised by an injector, or by pumps, into a channel through which it returns to the original tank. Several pickling vessels may be arranged side by side, in which case each reservoir will be placed in direct communication with every tub. When the wash waters become too highly charged with impurities, the first washings are set aside for extraction and replaced by the liquid previously used for the second washing, the second by the third and so on. When sufficiently saturated, the valuable metals contained are recovered *e.g.*, the copper from brass pickling by the addition of zinc, zinc oxide or carbonate, which precipitate copper, copper oxide or carbonate respectively.

—W. G. M.

A New or Improved Method of Extracting Tin from Iron in Tin Scraps and in Apparatus therefor. R. H. W. Biggs, London. Eng. Pat. 4584, March 28, 1887. 8d.

Hydrochloric acid at a temperature of 190—212° F. and a strength equivalent to 17° B., is introduced from an overhead cistern, with or without further dilution, into a revolving asphalte-lined metal cylinder, where it attacks the tin scraps. When these have been sufficiently stripped, the liquid is run into a tank beneath; the washings which are next obtained are then run into a series of tanks in which they are cooled to ensure the separation of any lead that may be present. Afterwards the tin is to be obtained by adding zinc or nitric acid and the sponge compressed and melted. Instead of rotators, tubs with revolving beaters, or other arrangements, may be employed.—W. G. M.

Improvements relating to the Production of Sodium and Potassium and to Apparatus therefor. O. M. Thowless, London. Eng. Pat. 12,486, Sept. 14, 1887. 8d.

To avoid the formation of compounds which, in the ordinary process of manufacturing sodium and potassium, tend to lessen the yield of metal, the caustic soda or other compound, itself heated, is introduced into previously heated carbonaceous matter. This is effected by setting the vertical retort containing the coke in a furnace, the flue of which passes beneath and thus warms a side chamber leading into the retort. This chamber is provided with a door for the introduction of the soda compound and with a sliding grating between it and the retort to regulate the supply of soda to the latter. On the opposite side of the retort is a covered hopper or chute for the admission of coke. Above all is a pipe leading to a condenser of the usual description. Beneath the retort is a door for the removal of ashes and for the purpose of cleansing.—W. G. M.

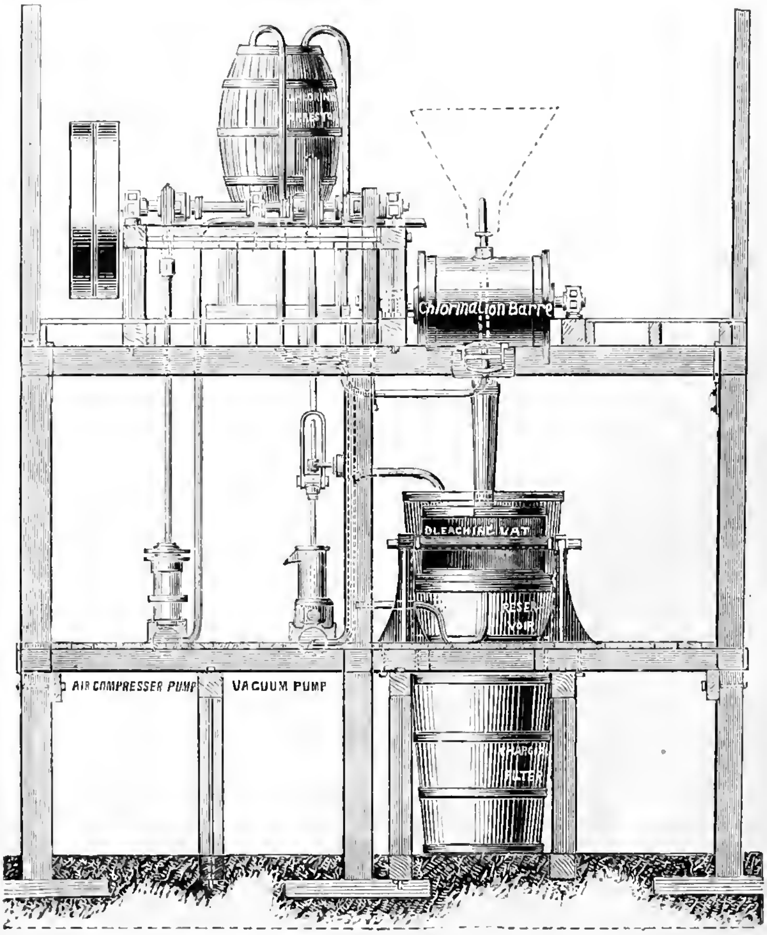
The Newbery-Vautin Chlorination Process. Engineering, **44**, 354—356.

This process, which is said to be in successful operation in Queensland as well as other places, for the extraction of gold, is based upon the fact that over 90 per cent. of the gold in roasted and crushed gold quartz is converted by the action of chlorine into soluble gold chloride, which may be removed by washing on a suitable filter, and that gold chloride on passing slowly through a charcoal filter suffers decomposition, the metal being left in the charcoal. When the latter is fully charged, it is burnt, and the ashes are fused with borax in a crucible, and a button or nugget obtained.

In the old styles of chlorination treatment, the time varied from 36 to 90 hours; now this is accomplished in from 3 to 6 hours. In the new process the chlorine is reduced to the liquid state under a pressure of 4 atmospheres, and the pressure applied not only makes it possible to obtain a strong solution of chlorine with the water in the revolving barrel, containing also the roasted and pulverised ore, but forces that solution into contact with the gold through every pore and crevice of the ore.

Should copper be present with the gold, the aqueous solution, after running through the charcoal filter, is brought into contact with scrap iron, by which any copper is precipitated. Silver will be found as chloride amongst the tailings on the filter, and it is proposed to remove it by washing with alkaline thiosulphate (hyposulphite).

Dry crushing is strongly recommended for treating the whole body of ore from a mine, and for this a stone-breaker should be used that will reduce the pieces to about ¾in. cubes if necessary. For subsequent crushing, Kroms rolls have proved very satisfactory. They will crush with considerable evenness to a 30 mesh, which is generally sufficient. The crushings are then roasted in the ordinary way in a reverberatory furnace, and the whole of the roastings are chlorinated as described. It is claimed that over 90 per cent. of the gold can be extracted at much the same cost as demanded by processes in general use, which, however, only extract some 50 per cent.



Referring to the cut, the crushed ore is put in the hopper above the chlorinating barrel, which revolves. The latter is made of iron, lined with wood and lead, and will stand a pressure of 100lb. on the square inch, and its capacity is equal to the reception of 30cwt. of ore. The charge falls from the hopper into the chlorinator, water, chloride of lime and sulphuric acid are added, and the manhole lid is fastened down. On the side of the barrel is a valve connected with an air-pump, through which air to the pressure of 4 atmospheres is pumped to liquefy the chlorine generated, after which the valve is screwed down. The barrel is revolved from one to four hours at the rate of ten turns per minute. The chlorinator is then stopped and the gas and compressed air is allowed to escape from the valve through lime-water, to prevent pollution of the air and to recover the chlorine. A glance at the figure will make the foregoing explanation clearer.—W. S.

XI.—FATS, OILS, AND SOAP MANUFACTURE.

Loss of Nitrogen in the Manufacture of Bone-fat and the Analysis of Bone-fat. H. Bornträger. Rep. Anal. Chem. **7**, 694.

BONES, after being crushed, are extracted with petroleum spirit under a pressure of two atmospheres in order to remove the fat. After distilling off the petroleum spirit it was found that the water originally contained in the bones passed over and that this contained on an average 0·64 per cent. of ammonia. The residual fat contains 92·2 per cent. of fat (good bone-fat should contain 95—96 per cent.) and 2·8 per cent. of ash, which consists of calcium carbonate and phosphate.—C. A. K.

A New Oil Plant. L. Richter. Landwirthsch. Versuchs. Stat. **33**, 455.

THE seeds of *Lallemantia iberica*, a plant belonging to the Labiatæ and found in the Taurus and Caucasus, contains 33·52 per cent. of fat, which has a specific gravity of 0·9336 at 20—21° and solidifies between 34 and 35°.
—C. A. K.

Vegetable Fats. H. Jacobson. Chem. Zeit. Rep. **11**, 218.

THE fats of the bean, vetch, pea and lupine contain considerable quantities of phosphorus by means of which the amount of the lecithin in them may be quantitatively determined. Bean-fat contains 19·27 per cent., vetch-fat 20·83 per cent., pea-fat 50·25 per cent. and lupine-fat 58·00 per cent. of lecithin respectively. The presence of lecithin in these fats can be further shown by the isolation of its decomposition product cholin. After saponification with caustic soda and extraction with ether, all the above fats yield cholesterin together with amorphous substances. The cholesterin thus obtained differs from that of animal origin in many of its properties, especially in its melting point. Pea-fat and lupine-fat contain small quantities of ceryl alcohol. The solid fatty acids of the above four fats consist mainly of palmitic acid and contain also other acids of higher melting point than stearic acid.—C. A. K.

Oxidation Products of Palmitic Acid. M. Gröger. Monatsh. Chem. **8**, 484—497.

THE oxidation of palmitic acid in alkaline solution gives rise to:—1. *Acids of the oxalic series:* Oxalic, succinic and adipic acids. 2. *Volatile fatty acids:* Acetic, butyric, caproic and caprylic acids. 3. *Oxy-fatty acids:* Oxyvaleric and dioxypalmitic acids. The more dilute the permanganate solution employed the higher the carbon value of the acids obtained.
—A. G. G.

An Improved Lubricating Composition. F. T. Archer, G. W. Hardy and F. J. Archer, London. Eng. Pat. 14,835, Nov. 16, 1886. 4d.

CAREFULLY-RENDERED tallow, Russian mineral oil, black antimony and gum camphor are mixed together warm and stirred while cooling.—W. L. C.

Improvements in the Manufacture of Lubricating Grease. W. Hicks. Eng. Pat. 1893, Feb. 7, 1887. 4d.

FIBROUS material of any kind, torn into shreds, is mixed with melted tallow, fat or grease.—W. L. C.

Improvements in Apparatus for Treating or Purifying Paraffin Wax. R. Tervet, Musselburgh. Eng. Pat. 4, Jan. 1, 1887. 11d.

THE novelty consists in the use of a series of narrow vertical "cells" or casings with "permeable sides," placed in a suitable heating chamber and arranged so that the heat may act on all sides. Metal moulds are fixed above the cells for receiving the paraffin wax in a melted condition and moulding it into suitable forms for being dropped into the cells. Bars with inclined sides are inserted between the cells and moulds, for closing the latter whilst the melted paraffin is being poured into them. The inventor also describes the construction and arrangement of the closing slides and accessory parts of the mould, as well as the slides for closing the cells and combining them with the other parts. The specification contains three sheets of drawings.
—D. B.

XII.—PAINTS, PIGMENTS, VARNISHES AND RESINS.

Improvements in the Manufacture of White Lead and other Lead Salts, and Apparatus employed therein, Parts of which are applicable to other Materials. J. C. Martin, Richmond. Eng. Pat. 1054, March 18, 1879 (Second edition). 8d.

THE specification describes improvements on Eng. Pat. 1300, April 4, 1877. The solutions of lead are made by dissolving in acetic, nitrous or other suitable acid small flakes or splashes of lead prepared by running the molten metal in thin streams upon a moving or stationary surface, such as that of an iron disc cylinder or cone, which is kept cool and wetted by jets of water or by occasional immersion in water. The second part of the invention consists in mixing hydrated lead oxide or lead suboxide with carbonate of lead to impart to the latter greater density and thus improve its quality for painting purposes. The mixing takes place when the materials are wet and the whole is ground up when dry, with or without the addition of more of the lead oxides, by means of apparatus which is fully described, with drawings, in the specification.—E. E. B.

A Process of Producing on Paper, Textile Fabrics, Wood, Leather, Skins and other light Materials a Transparent Waterproof Coating. F. H. Froedman, Dublin. Eng. Pat. 885, Jan. 20, 1887. 4d.

THE material is coated with a mixture of glue, gelatine or other colloidal substance, and either the bichromate of potash or of ammonia, dried and exposed to light to render the compound insoluble. The material is then placed in a bath of sulphurous acid, which renders the waterproofing compound transparent and almost colourless. The process of rendering gelatine insoluble by means of chromium salts is not claimed, but only the use of the sulphurous acid in connection with it.—E. E. B.

Improvements in Paints and Paint Compounds. H. J. Allison, London. From G. W. Banker, Brooklyn, U.S.A. Eng. Pat. 12,031, Sept. 6, 1887. 6d.

THE use of the oil extracted from the seed of Indian corn is claimed as a substitute for linseed or other oils now used for the manufacture of paints. The "corn" oil being one of the semi-drying oils, it is usually desirable to add a drier to it.—E. E. B.

Improvements in Waterproof Compositions or Paints. J. C. Lyman, London. From J. H. Lyman, Hadley, U.S.A. Eng. Pat. 12,632, Sept. 17, 1887. 4d.

THE compound is prepared by boiling "facticious or artificial maltha" (the solid residue which remains after the distillation of petroleum) with "benzine," and adding, in special cases, oil and turpentine, also some pigment such as Venetian red if a coloured product be desired. If the paint is liable to be subjected to a great heat, some non-combustible substance, such as asbestos, must be incorporated with it.—E. E. B.

Improvements in the Process or Method and Means for Rendering Fabrics and other Articles Water-repellant. Clara B. Warner, London. Eng. Pat. 13,593, Oct. 7, 1887. 4d.

THE solution is prepared by dissolving indiarubber in pentane and "benzine" in equal parts, and adding pentane or heptane. The articles are dipped into this solution, after it has been clarified by standing for a few days and by occasionally passing hydrobromic acid gas through, then drained in a chamber where evaporation is impossible, the solvent expelled by a current of steam or hot gases and the articles finally dried in the "finishing chamber," preferably by means of a current of hot air. Not only is the above process claimed, but also the use of wire gauze or bundles of wire in the pipes leading to and from the evaporation chamber, to prevent the possibility of an explosion in it; and, further, the use in the evaporation chamber of steam or gas from which the soluble solvent can be recovered by condensation.
—E. E. B.

XIV.—AGRICULTURE, MANURES, Etc.

Experiments with Manures on Summer Cereals. G. Andrae. Sächsische landw. Zeit. 1885, 791.

IN these experiments, Chili saltpetre, potash salts, and soluble phosphate were tried separately and mixed together:—(1) For barley, after potatoes lightly manured with dung, on a soil of medium quality; (2) for oats after similar crop and manuring, on soil 16 years in cultivation; (3) for oats after sugar beet on old cultivated land. The season was unfavourable. Only the Chili saltpetre, used by itself or mixed, yielded a profit.—D. A. L.

Destruction of the Ammonia Ferment. A. Ladureau. Annales Agronomiques, 1885, 522—525.

WITH the object of preventing the loss of nitrogen, as ammonia, from manure heaps, experiments were tried to arrest ammoniacal fermentation in solutions of urea by the addition of free phosphoric acid, superphosphate, lime, ferrous sulphate, phenol, sulphuric acid, boric acid, hydrochloric acid and ferrous chloride, but without success. Therefore the addition of magnesium salts is suggested, to fix the ammonia in the manure as ammonium magnesium phosphate.—D. A. L.

Field Experiments with Different Phosphates. Kremp. Braunschweig. landw. Zeit. **55**, 105—107.

THESE experiments were conducted with oats on a moderate loamy soil, containing 1·90 per cent. of humous matter, poor in lime and moderately porous. Superphosphate, bone manure and Thomas slag were tried separately and in conjunction with Chili saltpetre; the phosphates were without effect, but the nitrate produced a good increase in yield. Probably the soil had sufficient phosphoric acid in it beforehand.—D. A. L.

Effect of Lithium Salts on Vegetation. J. Gaunersdorfer. Landw. Vers. Stat. 1887, 171—206.

NUMEROUS investigators have worked on this subject and have come to different conclusions as to the effect of lithium on vegetable life. Focke found lithium a constant constituent of many plants and concluded that it was normal to some plants and accidental in some others when they were grown on a soil containing lithium. The author has made numerous investigations in this direction and found that lithium is always present in some plants (all varieties of Cirsium), but that these plants will develope quite normally without it, hence he concludes that it is not necessary to the existence of these plants and therefore is simply accidental although an almost constant constituent of such plants. Lithium is one of those substances which can act injuriously on vegetation; it checks development and causes pathological changes in the organs and to most plants even minute quantities are poisonous, the leaves becoming speckled with dried-up spots; and even those plants in which its presence is natural are affected in a similar manner sooner or later; this was proved by experiments with lithium sulphate on *Cicer arietinum.* When lithium is present in a plant not a trace is detected in young leaves, buds or organs of reproduction, as they are wanting in hardened portions, and only mere indications of it are observed in leaf-stalks, stems and roots; but it is found accumulated in the hardened woody fibres of fully grown leaves. Consequently by these leaves falling off, this objectionable metal is gradually removed both from the plant and soil; even plants which do not generally contain lithium can withstand a little in the soil, which, however, ultimately gets removed through the leaves. It is shown that lithium is carried upwards by the transpiration currents, but it can also move transversely through the hardened cell walls. In experiments with lithium sulphate on plants in the ground, it was found that merely watering with the solution was not sufficient to test the effect, since the lithium was retained in the upper layers of soil and was only gradually brought within root-range by subsequent watering with water.—D. A. L.

The Wild Potato of Paraguay. F. Nobbe. Landwirthschaftl. Vers. Stat. **33**, 447.

THE author finds that the composition of the tubers does not differ materially from that of ordinary potatoes.
—C. A. K.

Free Phosphoric Acid and Superphosphate. M. Weilandt. Landw. Versuchsstat, **34**, 207—215.

THE author has continued Ritthausen's experiments on this subject (*Ibid.* **20**, 401) and finds when dilute phosphoric acid acts on precipitated barium, calcium and strontium carbonates, more or less of the sparingly soluble dibasic salts are formed in accordance with the concentration of the acid solution and duration of the reaction. The salts produced are amorphous except when concentrated solutions of the acid are used. When a current of carbonic anhydride is allowed to act simultaneously with the phosphoric acid the amount of sparingly soluble salt formed is increased. Solutions of superphosphate act very energetically on marls and with less vigour on the crystalline forms of calcium carbonate, much of the phosphoric acid becoming sparingly soluble during the reaction.—D. A. L.

Experiments to decide whether Nitrates are essential for the Cultivation of Cereals. O. Pitsch and L. Campagne. Land. Versuchsstat, **34**, 241.

THIS is a continuation of former investigations and confirms the previous results. Cereals can develop completely and assimilate large quantities of organic substances and proteïn, when cultivated in ground which during their period of growth is quite free from nitric acid. The absence of nitric acid from the soil appears to hinder the growth of the portions of the plants above ground after they begin to shoot, for a time, but then they continue to grow readily and in a normal way. The root net-work was found to be exceptionally strong and extensive in the case of soil manured with nitric acid; more so than when manured with ammonium salts.—C. A. K.

Estimation of Ammonia Nitrogen in Soil and the Amount of Assimilable Nitrogen in Uncultivated Soil. A. Baumann. Landw. Versuchsstat, 1886, 247—303.

THE author, recognising the unsatisfactory nature of the methods of estimating ammonia in soils, has made a great number of experiments with the more usual methods.

Schlocsing's Method.—In the cold soda produces a continuous evolution of ammonia with humus soils. The amount of ammonia obtained from several samples of the same soil is almost exactly the same when the conditions of experiments are similar; hence with two samples of the same soil the results by this method agree whether the soda is in contact with both samples for 48 hours or for a week. It is evident that this method is not suitable for the estimation of ammonia in soils rich in humus: at any rate if employed at all, it is quite inadmissible to allow the soda to act more than 48 hours. When humus soils, after boiling with magnesia water, are treated with soda they yield considerable quantities of ammonia within 48 hours; soils free from humus do not behave in this manner. *Boussingault's method* the author finds is accurate, but the ammonia in the hydrochloric acid extract of the soil must be estimated azotometrically and not by titration. *Knop's azotometric method* is quite useless for soil analysis, inasmuch as the humus in the soil causes a contraction in the volume of gas produced and the greater the quantity of humus the greater this contraction becomes; even the addition of borax does not make the method usable. The author has therefore adopted the following method:—200grms. of soil are mixed with 100cc. of dilute ammonia-free hydrochloric acid (1:4). if the reaction is strongly acid 300cc. of distilled water free from ammonia are added, and the whole allowed to remain for two hours with frequent agitation; after filtering 200cc. of the filtrate (corresponding to 100grms. of soil) is transferred to the azotometer, about 5grms. of freshly ignited magnesia usta added and a current of ozonised air aspirated through the liquid, with frequent shaking, for ten minutes. The azotometric determination then proceeds in the ordinary way. The ozonising destroys the humus matter which would otherwise vitiate the results in the manner already noted above. Numerous ammonia determinations were done by this method. The amount of ammonia present in uncultivated arable soils varies with the character of the soil. Loamy soils are richest and those containing most clay also have the largest quantities of ammonia; chalky and sandy soils are poor in ammonia; but sandy soils rich in humus contain organic matter which is readily decomposed by soda in the cold, with evolution of ammonia. Such substances play a much more important part in vegetable nutrition than has hitherto been supposed when judging a soil; the amount of organic matter (vegetable) has, however, no influence whatever on the actual amount of ammonia in soil. The amount of ammonia-nitrogen in the most varied soils fluctuates between 0·004427grm. and 0·02894grm. per kilo. of soil. The amount of ammonia in an untilled and unmanured soil, judging from those kinds examined, appears to be a constant quantity and is scarcely altered by season or weather; it does, however, decrease with the depth. the ammonia being retained by the upper layers. Thus, from a depth of 1 to 25 centimetres the amount of ammonia is nearly uniform, from 40 to 45 centimetres there is a marked falling off, whilst at about 80 centimetres down only traces of ammonia are present.

Nitric Acid in Uncultivated and Unmanured Soils and Forest Soil:—The watery extracts were tested qualitatively with brucine and diphenylamine and when nitric acid was present it was estimated by the indigo method. Examination of numerous soils leads to the conclusion that uncultivated and unmanured soils contain an exceedingly small quantity of nitrates, more especially forest soils, which have frequently none at all or at the most only traces. Tests were made to a depth of 30 centimetres. The absence of nitric acid is attributed to low temperatures, dryness of the soils and condition of the nutritive matter being unfavourable for the development of nitrifying organism. Drainage experiments were made to illustrate how very small the nitrifying power is in soils free from animal matter and containing only small quantities of vegetable residues. Details are given showing the progress of these experiments; in course of the year the following amounts of nitric acid were obtained by draining the soils to a depth of 1·20 metres:—

Kind of Soil.	Nitrogen as Nitric Acid in Kilos. per Hectare.
Sandy soil	25·59
Loamy soil	20·90
Chalky soil (poor in humus)	50·24
Moor land (rich in humus)	4·17

In no case was either ammonia or nitrous acid detected in the waters.

At Rothamsted, a heavy, loamy soil, both unmanured and uncropped, has yielded in drainage water the following average quantities of nitrogen as nitric acid per annum, for eight years. Drainage from a depth of 40 inches (about 1 metre) 34·94lb. per acre (about 39·13kilos. per hectare); from 60 inches 38·90lb. per acre (about 43·57kilos. per hectare).

It is pointed out that the nitric acid produced in unmanured and uncultivated soil is not sufficient for the nitrogen requirements of forest trees, hence they must obtain their supplies of this element from some other source, either ammonia or possibly the easily decomposable nitrogenous organic substances referred to above. The fertile black soils of Russia, for example, contain large quantities of such organic substances, but frequently only traces of ammonia and nitric acid. When soil is boiled in hydrochloric acid the amount of ammonia obtained is 10 or 20 times the actual amount of ammonia in the soil and is derived from substances in the soil which doubtless bear a great resemblance to amides.
—D. A. L.

Field Experiments. J. Vollmer. Bied. Centr. **16**, 530—532.

The author's numerous experiments point to the fact that it is useless and wasteful to use manures in excessive quantities. In comparative experiments with different phosphates on sugar beet, Thomas-slag, amongst other phosphates, proved of value in a heavy loamy soil.
—D. A. L.

Changes in Composition associated with the Development of Bacteria in Drinking Water. T. Leone. Atti della R. Accademia dei Lincei, 1887, 37.

The author, like many other investigators, has observed that during the development of bacteria in drinking water, the organic matter decreases with the simultaneous formation of ammonia, but as the organic matter continues to diminish, the ammonia changes to nitrites and ultimately to nitrates. It is asserted that many kinds of micro-organisms are capable of producing these effects and the results are obtained either in open or closed vessels and with many kinds of bacteria mixed together, or with one kind by itself. With regard to denitrification—the addition of nutritive gelatin to a solution in active nitrification stops that process, and even the nitrates already formed are reduced; but, provided no more gelatin is added, in a few days (when the organic matter is decomposed) nitrification re-commences—the author infers that the same organisms are either denitrifying or nitrifying according to circumstances. He has confirmed this statement by numerous experiments with all necessary precautions in sterilised waters and with carefully cultivated and isolated bacteria. Although this would appear to attribute a double function to these organisms, it is pointed out that such is not the case, but that their function is one of oxidation throughout.—D. A. L.

An Improved Process of Making Manure. J. Roxburgh, Melbourne. Eng. Pat. 10,060, July 18, 1887. 4d.

Layers of sea weed, blood and slaughterhouse offal, cut-up carcases of horses, etc., night-soil and urine are placed in the order named in a vat and treated with sulphuric acid. When the action has ceased, the mass is turned over and sprinkled with lignite dust or "Hunter's deodorising disinfectant." The semi-liquid mass is removed to an asphalted shed and arranged in layers of two feet with stable manure in alternate layers of three inches. The heap is allowed to ferment for two or three months, then broken down and the large bones removed, bone dust added, in the proportion of 2cwt. per ton, and the drainage liquor sprinkled over the whole. It is again allowed to ferment for four or six weeks, then broken down and mixed with a further quantity of bone dust, preferably dissolved, and gypsum equal to 5 per cent. of the mass. In two or three weeks the composition is ready for use.—J. M. H. M.

Manurial Experiments with different Phosphates. W. Roberts. Journ. d'Agricult. Pratiq. 1885, 877—880.

Experiments were made with the same quantity of phosphoric acid in different forms on wheat, potatoes, roots and buckwheat. The results show the superiority of superphosphate and the comparatively small value of reverted phosphate. Taking two cases of wheat for example, the profit over the unmanured in francs per hectare was as follows: in the first case the grain only is considered; in the second the straw is allowed for as well:—

Form of Phosphoric Acid.	Profit.	
Superphosphate	11·00	153·20
Phosphorite (Ardennes)	21·05	52·80
Precipitated phosphate	—	49·60
Reverted	7·55	26·65

—D. A. L.

Composition of Cereals in relation to the Soil. A. Atterberg. Landw. Jahrb. **16**, 757.

The author finds as a result of his experiments that the quantity of mineral constituents in the plants increases proportionately with the quantity of mineral matter in the manure, while the rate of increase of the other nutritive substances remains quite regular. Further, that when the quantity of any one source of food at the disposal of the plant decreases, less of it is taken up and assimilated. If the result of this is a poor crop, the nutritive substances, other than that the supply of which has been decreased, will have increased proportionately and will be taken up in greater quantity by the plants. —C. A. K.

The Phosphatic Deposits of Santa Maria di Leuca in Southern Italy. K. Walther. Chem. Zeit. **11**, 1157.

Coprolites and remains of bones, which contain 35 per cent. of calcium phosphate, form 50 per cent. of the total mass of these deposits. There are two beds of the phosphatic material, which cover an area of 95,000 square yards, representing a deposit of at least 2,960,000 cubic feet. (See also this Journ. 1887, 668.)—C. A. K.

Obtaining Manure from Distillers' Spent Wash. W. S. Squire, London. Eng. Pat. 12,772, Oct. 7, 1886. 4d.

The wash is run into tanks, the suspended matter allowed to subside, the clear liquor run off and neutralised by milk of lime. The precipitate thus produced, rich in nitrogen and phosphates, is filter-pressed, dried and sold as manure.—J. M. H. M.

XV.—SUGAR, GUMS, STARCHES, Etc.

The Use of Poisonous Substances in the Manufacture of Sugar. C. Scheibler. Chem. Zeit. **11**, 1263—1264.

This is a paper on the question of the danger in the employment of barium compounds in the manufacture of sugar (compare *Chem. Zeit.* **11**, 1214), and the author states that although a patent was refused him in 1882 by the German Patent Office on the ground of the employment of poisonous substances being illegal, yet since that date patents have been granted in Germany for the use of lead and barium compounds for the above purpose. The author is of opinion that sooner or later serious consequences will result from the employment of these methods.—G. H. M.

Maltose and Dextrose. Degener. Deutsche Zuckerind. **11**, 1094.

Maltose, owing to its being free from dextrin, readily fermentable, rich in albuminoids and having a pleasant taste, is considered by the author to have a great future and likely to replace dextrose in brewing, baking and in the preparation of wine, liqueurs, artificial honey, etc., employed in the form of a syrup or semi-solid product. —C. A. K.

Formation of Sugar in Beet. Girard. Ztschr. f. Zuckerind. 1887, 672.

A series of experiments on this subject has been carried out on a specially prepared plot of ground. The weight of the root was found to increase regularly at the rate of 10—12grms. daily, the weight of fibre, ash and organic substances other than sugar, also increased regularly, while that of the sugar and water varied and in opposite directions, so that the increase in weight of sugar plus water was constant. Heavy rains do not decrease the quantity of sugar in the root as generally supposed, but may tend to hinder or to prevent its formation; the decrease is only proportional. The roots are free from dextrose, and contain from 1·45 per cent. after 10 days' growth to 12·19 per cent. after 120 days' growth of cane sugar. By determining the size of the roots the author concludes that the portion of beet below the surface must occupy a space of 6—8cb.m. The ash of the roots increases in weight from 0·15—0·20grm. daily. The proportion of fibre, ash, organic substances other than sugar, and water in the leaves increases regularly, that of water doing so despite varying atmospheric conditions. Cane sugar is not formed in the root from glucose or glycogen compounds, but is formed directly in the leaves under the influence of light. The quantity of glucose in the leaves after a definite period of growth is the same at the end of the day or night, while on the other hand that of cane sugar will amount at the end of a sunny day to 1 per cent. and diminish during the night to a half or more of that amount owing to its passing down to the root where it accumulates. The experiments were conducted in 10 plots of land, from which the crops were collected at intervals of 10—14 days, the maximum time of growth extending over 120 days. Details of the increase in size and weight of the various parts of the plant during these intervals are given.—C. A. K.

Direct Method of Extracting Sugar from Beet by means of Alcohol. Herzfeld. Ztschr. f. Zuckerind. 1887, 714.

The extract with methyl alcohol (this Journ. 1887, 669) contains after concentrating it to a syrup, altogether 6·18 per cent. of nitrogen, showing the presence of organic substances other than sugar. The alcohol distilled off contains acids which tend on further extraction of the beet to invert the sugar. On diluting the residue with water after distilling off the alcohol the fat of the beet separates as an oily layer. This contains fatty acids in part readily, in part difficultly soluble in ether. On analysis, it gave 70·4 per cent. of C and 11·13 per cent. of H. It consists only partially of crystalline fatty acids and is readily soluble in ethyl alcohol (especially absolute). The beet examined contained no optically active substances other than sugar.—C. A. K.

On the Examination of Sugar for other kinds of Sugar than Cane Sugar. Dingl. Polyt. J. **264**, 622—626.

I. Estimation of Invert Sugar.—It has already been shown that the method established not long ago by a Special Commission for the estimation of invert sugar will not fulfil all the conditions demanded of it. According to the *Ztschr. d. Rübenzucker-Industrie d. deutsch. Reichs*, H. Bodenberger and R. Scheller have been examining this method and have compared the results obtained thereby with those obtained by use of the so-called "Soldaini's Reagent," which has been recommended by Degener.

With regard to the Herzfeld method, the authors find that a very slight departure in the method of working from that originally described may lead to wide discrepancies in the final results. They find also that the results by this method are influenced by variations in the following conditions:—(1) Manner of heating and cooling. (2) Presence of cane sugar. (3) The presence of the so-called "Bodenbender's Substance." And further, that these influences can only be completely eliminated by a double copper estimation, a process too tedious and cumbrous for commercial work. They give, however, an exact description of how this process must be worked. The authors conclude, finally, that an exact determination of a small quantity of invert sugar in the presence of cane sugar cannot be made by the use of Fehling's solution. In its place they recommend the Degener-Soldaini reagent, which is essentially a solution of basic carbonate of copper in a double carbonate of soda. They claim for it the following advantages:—(1) It remains unaltered on long boiling and throws down no oxide of copper. (2) It is very sensitive to invert sugar. (3) Chemically pure sugar may be boiled with it seven minutes over a naked flame, or 12 minutes on a boiling salt-bath, before shewing any reduction. (4) The Soldaini reagent keeps much better than Fehling's solution. The authors describe minutely the method of preparation of this reagent and the mode of its titration and application to the estimation of glucose. By using artificially prepared glucose-solutions of known strength, the value of the reagent is obtained in terms of metallic copper, to which the copper precipitate is reduced in a stream of hydrogen gas. Finally the authors maintain that for qualitative work Soldaini's reagent is indispensable, and for quantitative work, though they are not prepared to say that it overcomes all difficulties yet they recommend it as the best known reagent. For the preparation of the foregoing reagents see original article.

II. Quantitative Estimation of Raffinose.—At the suggestion of Professor Tollens, R. Creydt (*Ibid.* 153—180) has investigated the problem of the estimation of raffinose in presence of cane sugar. He starts his investigation by determining for each of the two bodies separately the specific rotatory power before and after inversion, and works up his results into practically useful formulæ. For cases where the optical method is not applicable, as, for instance, in the presence of still other optically active bodies, he makes use of a method based upon the well-known property of raffinose to yield mucic acid on treatment with nitric acid.—A. J. K.

XVI.—BREWING, WINES, SPIRITS, Etc.

Recent Improvements in the Manufacture of Spirit. Dingl. Polyt. J. **264**, 452—456, 566—568: **265**, 324—330, 366—373, 410—416, and 460—467.

Reinke has examined a new apparatus devised by Möller for the purpose of removing the fusel oil from corn spirit. The apparatus is placed before the condenser and acts as a filter for the vapour, from which it removes the mechanically carried up particles of liquid. It has been practically employed in Westphalia with every success.

Rempel and Pampe's work on the causes of the formation of bad raw spirit has been already noticed (this Journal, 1886, 330).

Coltelloni proposes to pass the vapour through a series of vessels containing liquid paraffin, which will remove the fusel oil, etc. The paraffin can be regenerated by boiling with water and clay.

Bendix, in the *Zeitschrift für Spiritusindustrie*, 1886, 227, discusses the question of the employment of ozone for the production of a fine spirit and the removal of fusel oil. He also proposes to remove all the air from the pores of the charcoal employed for the removal of fusel oil by treating it in a current of superheated steam for 1½—2 hours, the subsequent filtration to be conducted out of contact with air. The process has been tested in Eisenmann's distillery with satisfactory results.

Pampe suggests the regeneration of charcoal by means of superheated steam. He obtains a temperature of 600—700°, which is sufficient to render both the tube and char completely red-hot. The charcoal must, however, not be in a fine state, but should be as large as peas, in order that the steam may penetrate between the particles.

Schneemann discusses the question of the advisability of drying the residual products and comes to the conclusion that for large distilleries it is perhaps advantageous, but for distilleries where there is a demand for it as fodder it is not to be recommended.

Riehe is of opinion that the diseases of cattle caused by the use of these residual products as fodder are due not to the processes of manufacture (fermentation distillation, etc.) but to certain substances which are already present in the raw material.

The poisonous action of the residues from potato spirit is ascribed by *Kassner* to the presence of solanidine, which is formed from the solanine present in the potato germ by the action of acids in the mash.

H. Müller Thurgau has investigated the action of diastase and invertase under varying conditions of temperature and pressure with the following results:—1. The influence of temperature on the amount of diastatic action judged by the amount of maltose formed can be expressed by the following proportional numbers: The action at 0° is not inconsiderable, at 10° it is three times greater, at 20° about five times, at 30° about nine times and at 40° about forty times greater than at 0°. This, for the above temperatures, gives the ratio 9 : 20 : 38 : 60 : 98. The invertive action at 0°, 10°, 20°, 30°, 40°, 50° and 60° is in the ratio of 9 : 19 : 36 : 63 : 93 : 131 : 163. The enzymic actions differ from most physiological actions, inasmuch as they take place at 0° and also, on the other hand, continue at a much higher temperature than the latter. 2. Carbonic acid exerts a marked influence on diastatic action at ordinary pressures and increases it three-fold. An increased pressure also causes a marked increase in the diastatic action, both when the liquid for conversion contains air and also when carbonic acid is present. With the former it requires a pressure of 15 atmospheres to double the action, whilst with the latter 3 atmospheres are sufficient to effect the same result and at ordinary pressure twice the amount of maltose is formed in the presence of carbonic acid. Diastase also exerts a much more energetic action on ungelatinised starch in the presence of carbonic acid. 3. The amount of cane-sugar in solution between the limits of 2 and 20 per cent. exerts only a very slight influence on the energy of the invertive action; at the higher concentration the inversion proceeds slightly more slowly than at the lower. The amount of invert-sugar formed exerts a considerable influence on the further progress of the action. Alcohol exerts an unfavourable influence on the action of invertase, the presence of 10 per cent. decreases the action by about one-half. A slight addition (0·014 per cent.) of tartaric acid has a favourable influence on the action of invertase, but 0·1 per cent. slightly retards the action and a larger amount has a very decided influence.

H. Goldschmidt has found at least *one* mould-fungus in the air which has a diastatic action; this action appears to be exerted during the earlier stages of its growth. The mould appears to be a *Penicillium glaucum*.

L. Cuisinier concludes that, since dextrose is found in barley and malt, there must be another ferment present besides diastase. He has discovered this ferment and calls it *glycase*; it is present in unmalted barley and is most active after the grain has been steeped. Glycase converts ungelatinised starch slowly into dextrose, and it also gives the same product with starch-paste.

L. Errara has detected glycogen in yeast; it is present in considerable quantities in yeast in active growth. He considers that the glycogen is decomposed in the self-fermentation of yeast.

Boutroux has observed an acid fermentation of glucose by a micrococcus which resembles *Micrococcus oblongus*. *Hydroxygluconic* acid, $C_{12}H_{12}O_{16}$, is formed: this acid is not identical with zymogluconic acid formed by Micrococcus oblongus. Maumené considers that hydroxygluconic acid is probably identical with one of the acids formed by the action of very dilute nitric acid on sugar.

F. W. Dafert concludes from his researches that starch is an organised, more or less changing mixture of a large number of chemical substances—starch-cellulose, granulose, dextrin, sugar, proteïn-substances, amides, etc. The greater part of these substances consist of starch bodies, which differ the one from the other. He concludes, therefore, that starch has no formula.

L. Sostegni has drawn attention to the differences which exist in the numbers given by different observers for the proportion of dextrose formed from starch by the action of acids. He has examined this point, using pure rice-starch; at a mean of 11 determinations he finds the ratio of starch to dextrose as 93·2 : 100, whilst Salomon found 93·5 : 100. The author also examined the substances which remain behind on dissolving starch by means of dilute acids or by soluble ferments. He found this consists of about 20 per cent. of a fat, chiefly free fatty acid. The residue, freed from fat by ether, consists of cellulose.

E. Grimaux and *L. Lefevre* claim to have converted glucose into dextrin by treating the former with dilute hydrochloric acid and treating the product, after evaporation, with 90 per cent. alcohol. The product still contains fermentable sugar, which may be removed by fermentation with yeast: it then has a reducing power of 17·8 and rotating power $[\alpha]_D = +97 \cdot 48°$. It somewhat resembles dextrin in properties.

A. Moller gives the results of experiments undertaken by Dr. Hamberg on the physiological action of fusel oil and other alcohols present in crude spirit. The latter finds that the intoxicating action goes hand in hand with the volatility of the substance, and that the injurious effect which follows the continued excessive use of spirits is due to the ethyl alcohol, and not to the fusel oil, when the amount of the latter present does not exceed the ordinary limits.

Wittelshöfer has contributed an article to the *Zeitschrift fur Spiritusindustrie* dealing with Henze's apparatus for mashing and distilling. Provided certain precautions are observed, this apparatus compares very favourably with that usually employed.

Petermann gives a series of analysis of the Jerusalem artichoke, of which the following numbers are the mean :—

	Maximum.		Minimum.		Mean.
Water	79·43	....	75·04	....	77·68
Carbohydrates convertible into sugar	16·37	....	12·72	....	14·33
Carbohydrates not convertible into sugar	7·12	....	3·93	....	5·37
Fat	0·26	....	0·11	....	0·18
Proteids	1·56	....	1·06	....	1·35
Ash	1·39	....	0·92	....	1·10
True albuminoids	0·91	....	0·69	....	0·79

Of the nitrogenous substances, 59·1 per cent. are present as true albuminoids, the remaining 40·9 per cent. consist of amides, peptones, etc.

G. Heinzelmann mentions some abnormal constituents of potatoes. In certain samples he found an unusually large amount of acid, as much as 0·7 to 0·9° acid, which checked the fermentation. He also found in some samples a considerable amount of *soluble* carbohydrates (sugar, dextrin, etc.) in potatoes.

The employment of St. John's bread for the manufacture of spirit is suggested. It is largely used in Portugal and the Azores for this purpose, as much as 4000 to 6000 litres of refined spirit being produced in Portugal daily. The composition of the locust is as follows :—

Total sugar	40·00	per cent.
Proteins	5·21	,,
Fat	0·55	,,
Tannic acid	1·82	,,
Butyric acid	1·30	,,
Organic matter free from nitrogen	20·00	,,
Ash	2·30	,,
Ligneous fibre	5·00	,,
Water	23·80	,,

The sugar consists chiefly of cane-sugar, with a little invert sugar. The manufacture of spirit is more difficult on account of the butyric acid present.

A. Ralu proposes to use batatas (*Batatus edulis*) for the production of spirit. In order to overcome the difficulties attending the manufacture of spirit in the Azores, he has patented a method by means of which he reduces the batatas to meal, and imports this meal into America. Alcohol can be produced much more cheaply from the batata meal than from maize, wheat, rye, or other cereals.

Various methods for preparing the potato-mashes for the production of raw spirit are treated of. The original should be consulted for this.

R. Rempel proposes to cultivate yeast for distilleries by growing it in a mixture prepared from the residues and a grain-mash. He claims that this procedure has several advantages over the ordinary method; the yeast is free from disease-organisms and the cost less. *Wittelshöfer* also treats of the influences affecting yeast growth and fermentative power in distilleries, and concludes that the temperature and amount of acid play an important part in the activity or otherwise of yeast.

A series of instances of bladdery-fermentation are quoted, which show that this is due not only to faults in the malt and in the yeast, but also to mechanical influences in the mash tun.

J. Ben describes a coal from Westerland which possesses considerable power in the defuselisation of raw spirit, when the latter is filtered through it; it is very porous.

Korth states that the injurious properties of spirit-residues may be removed by the evaporation of the residues under high pressure, and subsequent prevention of the formation of acetic and butyric acids.

W. Windisch proposes to detect small quantities of aldehyde in spirit by employing metaphenylenediamine hydrochloride as a reagent. A strong aqueous solution of the reagent is added to the liquid to be tested drop by drop; it sinks to the bottom on account of its gravity, and there forms a more or less intense yellowish-red to pale yellow zone, the depth of colour depending on the amount of aldehyde present. 0·0005 per cent. of aldehyde may be detected by this reaction. The *m*-phenylenediamine must be chemically pure and kept in a dry state: the solution should be prepared fresh each time. The coloured zone should appear at the latest in 3 to 5 minutes, since the purest alcohol will give the reaction on standing, aldehyde being formed by atmospheric oxidation.

The permissible error in alcoholmeters is discussed by a writer in the *Zeitschrift fur Spiritusindustrie*. He states that this may amount in instruments graduated in $\frac{1}{5}$ or $\frac{1}{10}$ per cent. to 0·32 per cent., and in instruments graduated in $\frac{1}{2}$ per cent. to as much as 0·74 per cent. He therefore recommends the use of the normal alcoholmeter, and also considers that the instruments used for determining liquids poor in alcohol, should only be graduated between the limits of 10 and 50 per cent.

Wittelshöfer discusses the various tables in use for calculating the amount of true starch from the alcohol formed. He gives the preference to those of Conradi.

G. Portion proposes, in order to obtain complete saccharification of the starch, and consequent full yield of alcohol in distilleries, to allow a diastatic action and the fermentation to go on side by side in the fermenting vessels. In this way the sugar is removed as fast as it is formed, and the action of the diastase is not stopped by the action of the products of conversion (compare Müller-Thurgau, above); both the conversion and the fermentation then go on to their full extent.—G. H. M.

Swedish Malting Barley. C. G. Getterlund. Allgemeine Braur. w. Hopfenzeit, 1887, 94—96.

Swedish barley compares well with barley from Moravia, Bohemia and Silesia, when the following points are taken as indicating a good malting barley. Short, full, hard, clear, pale-yellow grain, neither red nor dark at the top, 1000 weighing 45—63grm. or 65—75kilos. per hectolitre; internally white, mealy, loose, not glassy; the barley must be quite clean and not less than 90 per cent. germinate within 120 hours. On the average, water should not exceed 14·16 per cent.: ash, 2·6 per cent.: nitrogenous matter, 10—11 per cent.: husk, 8 per cent. Extractive matter should be at least 60—65 per cent. and phosphoric acid 0·614—1·45 per cent. of the dry barley. The author suggests that results from analysis of northern (Swedish, Norwegian, and Finnish) barleys indicate a more certain diastatic action than the southern barleys.

—D. A. L.

New Colouring Matter for Wine. Ztschr. f. Nahrungsmittel-Unters u. Hyg. 1887, 141.

The berries of *Aristotelia Magni*, a shrub found in Chili and belonging to the Tiliaceæ, have lately been used for this object in France. They contain tannic acid.

—C. A. K.

Omeire. R. Marlott. Arch. Pharm. 1887, 744.

This is a drink resembling koumiss, prepared by the natives in south-west Africa, by filling gourd bottles, which contain remains of fermented milk, with milk, shaking well and then allowing to stand. It is a thick, half-coagulated liquid, possessing a pleasant wine-like smell and a slightly-sour taste; it contains a little alcohol.—C. A. K.

Preparation and Composition of Brewers' Pitch. J. John. Allegem. Ztschr. f. Bierbrau. u. Malzfabr. 1887, 2.

In view of the great importance of pitch in continental breweries, the author considers that a full examination of the properties and composition of the substance should be made. Before all things, it is necessary that the pitch should not communicate any taste to beer, and it should neither be too soft, nor so brittle that it will fall off the walls of the vessels. The pitch most generally employed appears to be mainly composed of resin and resin-oil, and the above-mentioned properties depend upon the correct ratio of these being maintained.

—G. H. M.

Improvements in and Apparatus for the Manufacture of Ozone and its Application to the Purification or Treatment of Alcoholic Liquids and other similar Purposes. J. C. Mewburn, London. From L. Teilliard, Tournus, France. Eng. Pat. 15,175, Nov. 22, 1886. 8d.

The inventor has devised a method for the preparation of pure supersaturated ozone by triple "electrisations" of oxygen under pressure and apparatus for carrying this out. He applies the ozone so obtained to the purification and ageing of spirits, etc. Full details of the methods employed and drawings of the apparatus used for both purposes are given in the specification.

—G. H. M.

The Manufacture of Alcohol from Manioc or Improvements relating thereto. W. P. Thompson, Liverpool. From S. Bensaude, Paris, France. Eng. Pat. 15,896, Dec. 4, 1876. 6d.

The manioc roots, after they are taken up and cleaned, are cut into pieces of a suitable size and dried in the sun. The dried root is then readily transportable and will keep until it can be brought to Europe and transformed into starch. The extracted starch is converted into glucose and fermented in the ordinary way.—G. H. M.

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

(A) CHEMISTRY OF FOODS.

Value of Pig-nut Cake and of Cocoa-Meal in the Production of Milk. Stutzer and Werner. Landw. Jahrb. **16**, 819.

Cocoa-meal containing a quantity of albumen equivalent to that of pig-nut cake acts very favourably in increasing the amount of butter-fat and dry substance in milk. The taste and appearance of the cocoa-meal butter is far better than that of pig-nut butter, while it is harder and more yellow in colour. Cocoa-meal fodder is therefore to be recommended, especially since, for the same quantity of albumen contained it is only half the price of pig-nut cake.—C. A. K.

Poisonous Action of Castor-oil Cake. F. Benecke. Ztschr. österr. Apoth. Ver. 1887, 421.

Castor-oil cake is favourable for the development of germs. Microscopical examination revealed large quantities of germs in the cake and also forms resembling budding germs. The author, therefore, considers it probable that germs are indirectly the cause of the poisonous effect, the germs converting substances present in the seeds into others possessing poisonous properties. It may also be possible that this action is only a subsidiary one and that a non-organised ferment, by absorbing oxygen, is the cause of the decomposition.—C. A. K.

The Accuracy of Hehner's Method for Testing Butter. W. Fleischmann. Milch-Zeit. **16**, 731.

According to the investigations made up to the present the amount of so-called insoluble fatty acids in butter-fat is 85·5—89·8 per cent. and in other fats examined 95·22—96·10 per cent. of the weight of the respective fats when pure. Taking the mean of these percentages as a starting point, the author finds that the accuracy of Hehner's method when applied to testing a mixture of fats (butter-fat and oleomargarine) for oleomargarine, increases with the quantity of the impurity present. But when used for estimating the quantity of butter in a mixture of fats, the accuracy increases with a decrease in the percentage of butter.—C. A. K.

Additions to Investigations on the Fermentation of Cellulose. H. Tappeiner. Ztschr. F. Biologie, **24**, 105.

In previous investigations the author had found that the cellulose in the digestive canal of herbivora is decomposed by fermentation into fatty acids and gases. He has tried to induce such fermentation in flasks filled with cotton wool and a 1 per cent. solution of meat extract by inoculation with the contents of the intestine, the result being compared with that produced in flasks similarly filled without the cotton wool. Fermentation sets in soon after the inoculation, with the formation of fatty acids and the liberation of small quantities of carbon dioxide, hydrogen and marsh gas. The cellulose remains unchanged and the fermentation, which only lasts a short time, proceeds similarly in the flasks with and without the cellulose. In another set of experiments the flasks were filled with cotton wool, Nägeli's salt solution and asparagine and inoculated with the contents of the rumen. Fermentation took place, the cotton wool was dissolved and volatile acids, together with carbon dioxide and some hydrogen, were evolved, which must have resulted from the fermentation of the dissolved cellulose. Cotton wool added to a concentrated solution of asparagine does not dissolve when the latter is caused to ferment, being protected against decomposition by the fermenting asparagine. The fermentation is nevertheless quicker and more complete in presence of the cotton wool.—C. A. K.

The Reichert-Meissl Method of Testing Butter and its Application for controlling the Sale of Butter and its Substitutes. R. Wollny. Milch-Zeit. 1887, 32—35.

On the ground of numerous analyses, the author contends that the Reichert-Meissl method of estimating small quantities of butter in margarine is, in its present form (*Chem. Zeit. Rep.* **11**, 210), of no value at all. The sources of error are:—(1) the absorption of carbon dioxide during the saponification, which can introduce an error of 10 per cent.; (2) the formation of "esters" during the saponification, which may cause a loss of 8 per cent.; (3) the formation of "esters" during the distillation, involving a loss of 5 per cent.; (4) the effect of the coherence of the fatty acids during the distillation, which, in extreme cases, may cause a loss of 30 per cent.; (5) the form and size of the distillation apparatus and the time during which the distillation lasts, causing an error of ±5 per cent. The following modifications of the process are proposed, which render it perfectly reliable:—5grms. of the clear melted fat poured off from any sediment contained, is treated in a 300cc. round-bottomed flask, with 2cc. of 50 per cent. caustic soda solution (free from carbon dioxide) and 10cc. of 96 per cent. (by vol.) of alcohol, and the whole heated on the water bath for a quarter of an hour, the flask being connected with a condenser. At the end of this time the alcohol is distilled off, the flask being placed for half-an-hour in a water bath and 100cc. of distilled water added. The flask is then kept for another quarter of an hour in the water bath and protected against the absorption of carbon dioxide. The clear soap solution is next treated hot (boiling), with 40cc. of sulphuric acid (30—35cc. = 2cc. of the caustic soda used) and two small pieces of pumice added. The flask is immediately connected with a condenser, a tube bent twice at an angle and having a bulb being interposed between the two. A gentle heat is applied until the insoluble fatty acids are melted, when the temperature is raised and 110cc. of liquid distilled off. This should occupy half-an-hour. The distillate is well shaken, filtered and 100cc. titrated with decinormal baryta solution, using phenolphthaleïn as indicator. From the number of cc. used, multiplied by 1·1, the result of a blank experiment, conducted under the same conditions (without the fat), is to be subtracted. This should not exceed 0·33cc. The exact size of the various apparatus used is stated.—C. A. K.

Casein and the Action of the Rennet Ferment in Cows' Milk. F. Schaffer. Landw. Jahrb. d. Schweiz.

Engling's conclusion that milk casein is a compound of albumen with calcium phosphate is confirmed by the author. Casein precipitated by rennet contains 5—8 per cent. of ash, consisting almost entirely of calcium phosphate. The calcium phosphate compound of albumen is readily decomposed by mineral acids and by acetic acid, so that casein precipitated by the latter only contains traces of ash. Small quantities of lactic acid produce the same result, for which reason casein obtained from milk that has stood for some hours contains less ash than that from fresh milk. The compound of calcium phosphate and albumen is present as a soluble substance in fresh milk and by the action of rennet it is converted into an insoluble body (casein). This action is purely a chemical one: it consists in the conversion of the tricalcium phosphate compound into one of albumen and acid calcium phosphate, and can be brought about by carbon dioxide. Rennet, which does not precipitate boiled milk, does so if after boiling, the milk is treated with carbon dioxide; the coagulation of milk by rennet is quicker in proportion to its acidity. Rennet alone cannot convert the tricalcium phosphate compound into the acid calcium phosphate one, the presence of a small quantity of acid being necessary for the change. The action of acids—*e.g.*, of acetic acid—differs from that of rennet, inasmuch as the acid calcium phosphate compound formed is further decomposed, so that finally an albumenoid substance free from ash results; this further decomposition is not effected by carbon dioxide. As the action of rennet in coagulating milk depends upon the freshness of the latter, the author proposes to examine milk by treating 100cc. with 2cc. of a solution made by dissolving a Hansen rennet-tablet (smallest number) in half a litre of water and determining the time required for coagulation at 35° C. With fresh milk this should not be less than 10 nor more than 20 minutes.—C. A. K.

Improvements in Processes for Preserving Crustacea and Certain New and Useful Chemical Solutions of Special Utility in such Connection. J. C. Mewburn, London. From J. J. Bate, Brooklyn, U.S.A. Eng. Pat. 8063, June 4, 1887. 6d.

One pound of boracic acid is added to 6lb. glycerin and 16galls. of water, and, preferably, also ¼lb. of bicarbonate of soda. The boracic acid may be replaced by 1lb. salicylic acid, or a mixture of the two acids. Crustaceæ boiled in this solution will keep for a longer period than if boiled in plain water. The flesh may be removed from the shells after boiling and "tinned" in the usual way, or the body in its entirety packed in some of the solution in an air-tight case. Either of these methods ensures the sound condition of the crustaceæ for a comparatively long period.—C. C. H.

(*B*) SANITARY CHEMISTRY.

On the Causes of Corrosion of Lead Pipes by Water. Max Müller. J. Prakt. Chem. 36, 1887, 317—340.

The extensive application of lead pipes for water-conducting purposes gave rise to many investigations on the action of water on lead, in order to find out the causes which lead to the frequently occurring destruction of lead pipes. The author attacked the same subject from a new point of view, by giving special attention to the nature of the gases dissolved in the water and their action on lead in the presence of saline matters. It is well known that distilled water, prepared in the usual manner, strongly attacks lead, with the formation of a bulky white precipitate, consisting of lead oxide, carbonic acid and water. One-third of a cubic metre of river water was distilled and portions of the distillate were taken at the commencement, middle and end of the distillation. The river water contained 0·00015 per cent. of ammonia. The three fractions were tested for dissolved gases, with the following result:—

Fraction.	Volume per cent. I.	II.	III.
NH_3	0·00115	0·0001	0·00008
CO_2	1·159	0·178	0·025
O	0·269	0·316	0·232
N (by difference)	0·612	0·702	0·513

These tests show that both ammonia and carbonic acid are chiefly contained in the first fraction, whereas oxygen and nitrogen are rapidly taken up by the distillate while exposed to the air. Lead strips were then suspended in the three fractions. After 24 hours the lead in Fraction I. was scarcely attacked. It was covered with a very thin greyish skin, but the water remained clear. Not so with the other fractions, the water being turbid and the lead perceptibly corroded. In order to find out the cause of the different behaviour of Fraction I.—which could be ascribed to the presence of a certain amount of ammonia or carbonic acid, or both—water free from ammonia was distilled and the distillate similarly divided in three fractions. The Fraction I. was again inactive on lead, whereas the Fractions II. and III. attacked strips of lead. These observations led to the conclusion that minute traces of ammonia do not corrode lead; the corrosion—*i.e.*, the formation of a white lead precipitate—rather depends on the amount of carbonic acid and oxygen present. Indeed, direct experiments, minutely detailed in the original paper, show that water containing twice as much carbonic acid as oxygen attacks lead most energetically. If carbonic acid be absent and oxygen present in the water, its action on lead is very feeble, whereas no perceptible corrosion takes place, if the water containing a normal amount of oxygen—about 0·3 per cent. by volume—also contains about 1½vols. per cent. of carbonic acid. These phenomena account for the fact that distilled water in the fresh state often shows another behaviour after a few days' standing. The Fraction I., at first inactive on lead, became active after some time—evidently from a loss of carbonic acid and absorption of oxygen. It was to be expected from these experiments that water containing neither carbonic acid nor oxygen would not attack lead; and this is, indeed, the case. As to the composition of the compound formed by the action of carbonic acid, oxygen and water on lead, the author could get no definite result, although one analysis showed $H_2O = 3·49$ per cent.; $CO_2 = 11·89$ per cent.; $PbO = 84·41$ per cent. In all the cases, where the water attacked lead, a small amount of the latter was found in solution and could be detected with sulphuretted hydrogen or potassium sulphide. If such water—although it was clear to begin with—be warmed, or even shaken with air, it turns turbid and forms a slight white precipitate. The solution of the lead proceeds very slowly; not until after the lapse of 24 hours are small traces to be found in solution. After three days the amount of lead in solution reaches its maximum, then it gradually decreases, until after a week or a fortnight all the lead has turned insoluble again. Most probably the basic lead carbonate is at first dissolved in an excess of carbonic acid; by and by a new formation of lead oxide takes place, which combines with the carbonic acid previously in excess, and the carbonate, deprived of its solvent, is thus precipitated. Previous investigators evidently overlooked the important part played by the carbonic acid and oxygen dissolved in water, and this circumstance accounts for their contradictory statements as regards the action of soft water on lead. The author also investigated the action of saline matters usually found in waters of natural origin. Small quantities of free ammonia in water quickly attack lead, but if carbonic acid is present at the same time, thus forming a carbonate or bicarbonate, no corrosion takes place. This statement, however, is only true as long as the quantities present are very minute; any considerable amount of ammonia will certainly dissolve lead. In the presence of air, a solution of the hydrate of calcium or sodium quickly attacks lead, which is soon found in solution and gradually forms deposits of small crystals. If air be excluded, no action on the lead takes place. We often find in buildings lead pipes embedded in cement or lime mortar, and the frequent destruction of the pipes gave rise to an opinion amongst builders that lead pipes must not be brought in direct contact with lime or cement. It is difficult to see how dry lime could corrode lead pipes, and the author thinks that in all cases in which a corrosion of the pipes has taken place the destruction may be traced to the simultaneous action of water. Wherever the presence of water can be excluded, no fear need be entertained for the safety of lead pipes. If free carbonic acid be rigidly excluded, sodium carbonate attacks lead, which is found in solution after some time. But the presence of free carbonic acid alters the whole state of affairs. Not only does sodium bicarbonate not attack lead, but it makes even active water inactive. This action of sodium bicarbonate is so characteristic and intense, that the addition of a small quantity of bicarbonate at once precipitates all the lead in solution. It was mentioned previously that lead carbonate is dissolved by free carbonic acid; but this statement must now be modified by the addition ot the words—if sodium bicarbonate be absent. This salt is, therefore, an excellent means for protecting lead from corrosion. River and surface waters nearly always contain calcium bicarbonate in solution and as this compound behaves the same towards lead as sodium bicarbonate, its presence, even in small quantities, protects the lead. A solution of gypsum attacks lead; but if, at the same time, calcium bicarbonate be present (as most frequently will be the case in river water), no lead goes in solution. The very same may be said of solutions of chlorides and nitrates; both dissolve lead only in the absence of a soluble bicarbonate. Organic matters will be found in river water in too minute quantities to have any effect on lead. But it should not be forgotten that surface water is frequently contaminated with sewage that may contain large amounts of ammoniacal compounds, which will dissolve lead under all circumstances. The conditions under which water will take up lead from lead pipes are therefore very simple and by an analysis of the saline matters this can now be ascertained beforehand.—S. H.

Improvements in Purifying Sewage and other Foul Liquids and in making Oil, Alkali, and Cement from Sewage Precipitate, and in Apparatus for that Purpose. W. Burns, Leith. Eng. Pat. 15,222, Nov. 23, 1886. 8d.

THE sewage is purified, firstly, by the injection of gaseous HCl; this is followed, secondly, by the injection of SO_2; and, thirdly, by the injection of chlorine. It is then successively passed through charcoal and peroxide of iron, chalk, clay and finally coal-dust and caustic lime. The sewage thus defecated is allowed to settle in tanks, the effluent from which is run on to a filter, composed of charcoal and iron turnings. The sludge is drained, made into bricks and calcined in retorts; the gaseous products are utilised and the cinder rendered into cement.—C. C. H.

An Improved Deodorising, Decolorising and Filtering Medium. O. Bowen and J. Cobeldick, London. Eng. Pat. 15,240, Nov. 23, 1886. 6d.

SHALE, such as found at Lyme Regis, is broken into about 1in. cubes, mixed with 15 per cent. of alumina or aluminous earth and furnaced from four to six hours at a temperature of 900—1200°F. The product is used as a filtering media for the purification of sewage; when exhausted, it can be regenerated by a fresh furnacing with 20 per cent. of alumina.—C. C. H.

XVIII.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

An Improved Method of Galvanising Iron and Steel. J. T. Dann, London. From A. Schaag and Messrs. Flürscheim and Bergmann, Eisenwerke, Germany. Eng. Pat. 14,020, Nov. 1, 1886. 4d.

ACCORDING to this method, the zinc is electrolytically deposited upon the article to be coated from a solution of any salt of zinc with any salt of magnesia, mixed in variable proportions, anodes of zinc being used. Bichloride of mercury or muriate of ammonia may be added to expedite the process.—B. T.

A New or Improved Galvanic Battery. A. Wunderlich and O. Eisele, Brussels, Belgium. Eng. Pat. 14,286, Nov. 5, 1886. 8d.

ON a revolvable shaft are placed—first, a disc of copper or carbon; then a disc of zinc insulated from it. The space between the two is divided up into sectorial compartments, which hold the exciting liquids. Next, another plate of copper is put on with the zinc, and then a plate of zinc arranged as above. This is continued as far as convenient. The exciting fluid falls from jets in a trough above into the sectorial compartments and turns the whole like a water-wheel. There is thus a continual movement of liquid. The current is collected by brushes from the zinc and copper plates, which form the ends of the series.—E. T.

Improvements in or connected with Means and Apparatus for the Deposition or Obtainment of Metals by Electrolysis. F. E. Elmore, Cockermouth. Eng. Pat. 15,831, Dec. 3, 1886. 6d.

LIQUOR, rich in the metal to be deposited, is supplied to the surface of the cathode in the form of a spray, and the metal, as it is deposited, is pressed and rubbed by burnishers of suitable material, such as agate, which produce a fine, compact deposit and remove occluded gases. Moving or stationary cathodes are employed in combination with stationary or moving burnishers.—B. T.

Improvements in and relating to Secondary Batteries. H. H. Lake. From A. V. Meserole, New York, U.S.A. Eng. Pat. 4311, March 22, 1887. 6d.

THE inventor immerses plates of zinc and lead in a solution containing a suitable salt of mercury, sulphate of zinc and sulphuric acid. On passing a current through, mercury and zinc are deposited on the zinc plate in a spongy condition and are then able to occlude hydrogen very readily. The lead plate, which may be amalgamated, is peroxidised. The sponge may also be formed in other ways. This cell has an E.M.F. of three volts and suffers very little from local action.—E. T.

Improvements in Secondary Batteries or Accumulators. L. C. E. Lebiez, Paris, France. Eng. Pat. 7975, June 2, 1887. 4d.

THE inventor employs as positive electrode, carbon or other suitable material, on which peroxide of manganese has been deposited by electrolysis of a solution of a manganese salt, such as manganese sulphate. He employs a solution of the same salt as exciting liquid and zinc, or lead coated with zinc, as the negative electrode. Such cells are said to be readily formed, are light and the positive electrode is very durable.—E. T.

Improvements in Primary Voltaic Batteries, and in the Preparation of the Elements and Solutions employed therein. W. Webster, London. Eng. Pat. 16,151, Dec. 9, 1886. 8d.

THE elements employed in this battery are zinc, immersed in dilute sulphuric acid, and carbon, either wholly or partially platinised, or platinised metal in a solution of nitrate of soda, sulphuric acid and water, in varying proportions, with or without the addition of chromic acid, or bi- or tri-chromates. The porous cells are partially coated with paraffin wax to prevent too rapid an interchange of the two solutions. The connections are made by means of mercury cups on the outer cell of the battery, so arranged as to enable any single zinc or carbon to be removed without interfering with the working of the battery. A compound siphon is employed to empty or fill several cells at once.—B. T.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Preparation of Menthol and Borneol. E. Beckmann. Chem. Zeit. **11.** 1265.

MENTHOL is obtained by cooling peppermint oil and recrystallising from alcohol the solid portion which separates out. The fluid product, which has been incorrectly described as menthan, or a fluid isomer of menthol, still contains a great deal of menthol dissolved in menthon, a substance which has also been obtained by Moriya and Atkinson by the oxidation of menthol, and which is easily converted into menthol. It has the composition $C_{10}H_{18}O$, and stands in the same relation to menthol ($C_{10}H_{20}O$) that camphor ($C_{10}H_{16}O$) does to borneol ($C_{10}H_{18}O$). The separation of menthon and menthol can be effected by hydroxylamine, which, when added to the alkaline solution of the mixture, converts the former into menthoxime, and leaves the latter unaltered. The menthol can then be obtained by dissolving the menthoxime in aqueous acid, from which the menthon very slowly separates as a colourless oil. In this way it was found that the greater part of the fluid residue from the preparation of menthol from Japan oil contained about 40 per cent. of almost pure menthol and 60 per cent. of menthon, and also that menthon is present to a considerable extent in American, as well as in Mitcham, peppermint oil. Menthon may be converted into menthol by treating it with sodium in ethereal solution. The first product of the action of sodium is a mixture of sodium menthol and sodium menthon; this latter, when treated with a further quantity of sodium and menthol, is completely converted into sodium menthol, from which the menthol can easily be separated. The easy conversion of the menthon of peppermint oil into menthol is of value in the preparation of menthol, and also for the improvement of the oil. By reduction, the bitter constituent can be removed, and the odour improved. Laurel camphor can also be easily converted into borneol, or borneo-camphor, by this treatment, and the employment of this substance, which is superior to ordinary camphor on account of its smell, taste, etc., need no longer be deferred on account of the difficulty in obtaining it.—G. H. M.

Erigeron Oil. F. Power. Pharm. Rundsch. 1887, 201.

THE ethereal oil of *Erigeron canadense*, obtained by rectification of the crude oil, boils at 176°, is colourless, neutral towards litmus and has a specific gravity at 15° of 0·8498. Its composition is $C_{10}H_{16}$: it is, therefore, a terpene.—C. A. K.

Erechthites Oil. F. Power. Pharm. Rundsch. 1887, 202.

THE oil of *Erechthites hieracifolia* is, when rectified, a colourless, strongly refractive liquid, boiling at 185—190°. It is a terpene, but by reason of its boiling point, probably belongs to the sesqui-terpenes—$C_{15}H_{24}$.—C. A. K.

Some Higher Homologues of Cocaïne. F. Nory. Pharm. Rundsch. 1887, 208.

COCAÏNE is the methyl ether of benzoyl ecgonine, and readily yields the latter on saponification, according to the equation—

$$C_{17}H_{21}NO_4+H_2O=C_{16}H_{19}NO_4+CH_3.OH.$$

Conversely, benzoyl ecgonine treated with methyl iodide and methyl alcohol yields cocaïne. With higher alkyl-iodides, higher homologues of cocaïne result. Merck has thus prepared the ethyl ether of benzoyl ecgonine, a body having the same physiological properties as cocaïne. The author has prepared monobromethylbenzoyl ecgonine by treating benzoyl ecgonine in a sealed tube with ethylenedibromide. It is an amorphous body, soluble in alcohol and water, insoluble in ether. Propylbenzoylecgonine is obtained by the action of propyl iodide and propyl alcohol on benzoyl ecgonine; isobutylbenzoylecgonine is similarly prepared. These are both crystalline bodies, possessing a very bitter taste and a powerful anæsthetic action.—C. A. K.

Solubility of Iodol in Ethereal Oils. E. Hirschsohn. Pharm. Ztschr. Russl. 1887, 513.

VARIOUS turpentine oils and other ethereal oils show differences in their power of dissolving iodol, so that this property may be applied in detecting adulterations. Iodol is least soluble in the oils of the coniferæ, the oil of the Siberian larch and that of the screw-pine being the only ones that dissolve it readily. The oils of the Aurantiæ show different solubilities and may be thus distinguished one from the other. 1grm. of iodol dissolves in 10cc. of curaçoa oil, in 30cc. of orange oil, and in about 50cc. of orange-peel oil; 40cc. of the latter are necessary when mixed with 20 per cent. of orange oil to dissolve 1grm. of iodol. The oils of the Compositæ and Labiateæ show the greatest solubility, but when admixed with oils of the coniferæ the solubility is considerably lessened.—C. A. K.

The Constituents of the Scopolia Root. Henschke. Ztschr. f. Naturwissensch. 1887, 103.

TWO new alkaloids, *Scopoleïn* and *Rotoin*, have recently been prepared on a manufacturing scale from *Scopolia japonica* (Japanese belladonna). The former was obtained by Eykmann, who also isolated a glucoside scopolin and a decomposition product of the same, scopoletin. The author finds that *Scopolia japonica* does not contain any new alkaloids, but mixtures in varying quantities of atropine, hyoscyamine and hyoscine. The commercial rotoin is not a base but a mixture of the sodium salts of fatty acids rich in carbon. Scopoletin is identical with the constituent of Atropa belladonna called chrysatropic acid (Kunz).—C. A. K.

Saccharine. Ztschr. f. Rübenzucker Ind. **36**, 949.

A REVIEW of our present knowledge on the subject (compare this Journal, 1886—75, 349, 359, 421, 546 and 616). The solubility of saccharine is increased if the solution is neutralised. Saccharine melts at 200° with partial decomposition, and yields a strong odour of bitter almonds. Saccharine has a strong antiseptic action. Stutzer found that meat-peptone solution, which developed bacteria in 12 hours, did not do so for 24 hours when 0·01 per cent. saccharine was added, whilst 0·02 per cent. prevented any growth for 40 hours, and 0·04 per cent. for 60 hours. Solutions of sugar, containing potassium phosphate and ammonium nitrate remained sound for 72 hours in the presence of 0·10 per cent. of saccharine.—G. H. M.

The Preparation of Iodised Oil. H. G. Macalister and W. Stewart, Glasgow. Eng. Pat. 13,865, Oct. 29, 1886. 4d.

OIL (kind not stated) is agitated with one-fifth of its weight of strong sulphuric acid, and after subsidence is washed with water or a saline solution. After a second subsidence, a small quantity of an alkaline solution (at about 20° Tw.) is added, with constant stirring. It is claimed that with oil thus treated, an alcoholic solution of iodine may be readily incorporated.
—W. L. C.

Improvements in the Preparation of Oils for Medicinal Purposes. H. Mackay. Eng. Pat. 14,729, Nov. 13, 1886. 4d.

Pure cod-liver oil is mixed with 3 per cent. of essence of hops.—W. L. C.

XXI.—EXPLOSIVES, MATCHES, Etc.

Report on the Circumstances attending a Fire and Explosion at Messrs. Roberts, Dale & Co.'s Chemical Works, Cornbrook, Manchester. Gov. Rep. No. lxxxi. Colonel V. D. Majendie, C.B.

This exhaustive report shows that the articles manufactured on the side of the works where the explosion occurred, were picric acid, nitrate of lead, nitric acid, hydrochloric acid (nitre cake and salt cake), tin crystals, tin solutions, nitrate of iron, nitrate of copper, aurin, Manchester brown, Manchester yellow, lakes for paper stainers and emerald green. Such raw materials as carbolic acid, sulphuric acid and litharge, the litharge being used for making nitrate of lead, were all present, the latter salt in very considerable quantity; some nitrate of strontium was also present.

A fire commenced the catastrophe, this breaking out at or near the stove used for drying the picric acid. The fire spread quickly, and in five or six minutes an explosion followed, but not one of an alarming character. This explosion came from the site of the picric acid stove as nearly as it can be located. It was followed in something under a minute by a second explosion of an appalling character, and attended with disastrous results in the shape of damage. One life was lost.

There is little doubt that the fire was caused by the carelessness of a workman, who was smoking. Several theories are advanced to explain the first and lesser explosion, but the second, which was so disastrous, was in all probability due to the blazing and molten picric acid coming in contact with the litharge placed in close proximity and with the nitrate of lead and nitrate of strontium. It would at once combine with these and form fearful explosives. Picric acid alone can scarcely be called an explosive, but if it comes in contact even with plaster or lime, it forms a picrate of highly explosive character, and it is shown that picric acid mixed with a little litharge in the cold, produces a mixture which explodes much more readily than picric acid alone.

Finally, the precaution is urged, that in the manufacture of picric acid the separation of the acid from all other substances or ingredients, contact with which would be likely to produce under favourable conditions a *picrate* or explosive mixture should be carefully seen to.

"At present picric acid and picrates appear to fall within the category of 'explosives,' and to be subject to the Explosives Act, 1875, only when they are 'used or manufactured with a view to produce a practical effect by explosion or pyrotechnic effect.'"

"In view of the present disaster," Colonel Majendie proceeds, "and of the results of my experiments it will be a matter for careful consideration whether it is not necessary in the interests of public safety to take advantage of the powers conferred by the 104th section of the Explosives Act, 1875, and to extend the definition of explosive to picric acid and all picrates, for whatever purposes manufactured, and to apply the same provisions of the Act, subject to such exceptions, limitations and restrictions as may appear reasonable. This point, however, is one which, in the interests of the trade, as of the public, demands the fullest and most careful consideration."

As to the storage together and in close proximity of the several substances which resulted in the formation of such fearful explosives, Colonel Majendie stigmatises it as the result of negligence.—W. S.

XXII.—ANALYTICAL CHEMISTRY.

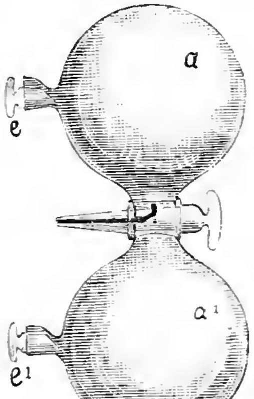
Congo Red as a Reagent for Free Acid. C. Wurster. Centralbl. f. Phys. **11**, 240.

E. Brucke (*Chem. Zeit.* 11, 315) concludes that since human urine does not affect Congo red solution, it does not contain any free acid or carbon dioxide. The experiments of the author show that the presence of ammonia or ammonium salts interferes with the reaction between congo red and acids, and therefore that as a means of proving the presence or absence of free acid in organic liquids such as urine, where ammonia cannot be excluded, it is valueless. Carbon dioxide, acetic acid and other organic acids have not the least effect on congo red in presence of even small quantities of ammonia or ammonium salts; the cause of this is that these acids are not able to decompose the ammonium salt of congo red. The action of inorganic acids is also interfered with by ammonium salts. Several drops of hydrochloric and dilute sulphuric acid can be added to a solution of Congo red in glacial acetic acid before any change in colour takes place, and then this only takes place gradually; a considerable quantity of the acid must be added before the blue coloration forms.

—C. A. K.

Separating and Extracting Apparatus. R. Schütze. Chem. Zeit. **11**, 1159.

The aim of the apparatus is to prevent the loss of solution which occurs during extraction and separation. a and a^1 are two glass vessels, either of the same size or of different sizes, connected by a three-way cock (as shown in figure). Tubulures e and e^1 fitted with stoppers, are fixed in the side of the vessels a and a^1; the edges of the tubulures are in part bent back, and the stoppers are provided with a hole, or are ground unevenly, so as to admit of the vessels a and a^1 being connected with the air by placing the stoppers in a certain position. The solution to be extracted, together with the extracting medium, is placed in either of the two vessels, the stop-cock between the two being closed. After extraction, e and e^1 are opened and the extract run from the one vessel to the other. The process can, of course, be repeated as required; the liquids can be poured off through e, e^1 or the three-way cock.



—C. A. K.

Laurent's New Polarimeter. Kanders. Oesterr. Ztschr. f. Zuckerind. **16**, 645.

This is a half-shadow instrument; it has a scale of saccharimeter degrees from −200 to +400, and a divided arc from −45° to +90°. The verniers are so arranged that 0° on the scale corresponds to 0° on the divided arc, and 100° on the former to 21° 40′ on the latter. The normal weight of sugar, which dissolved in 100cc. of water rotates 100°, is stated at 16·2grms (16·315grms. Kanders), while with the ordinary Laurent's polarimeter it is 26·048grms., so that the new form is 1·6 times more accurate. The results are reliable to 0·05°, and by having the scale extending to 400° very concentrated solutions may be examined directly; also by examining normal solutions in tubes 400mm. long further exactitude may be attained. The author has determined the specific rotary power of sugar with this instrument, using solutions containing varying quantities of sugar per 100cc.

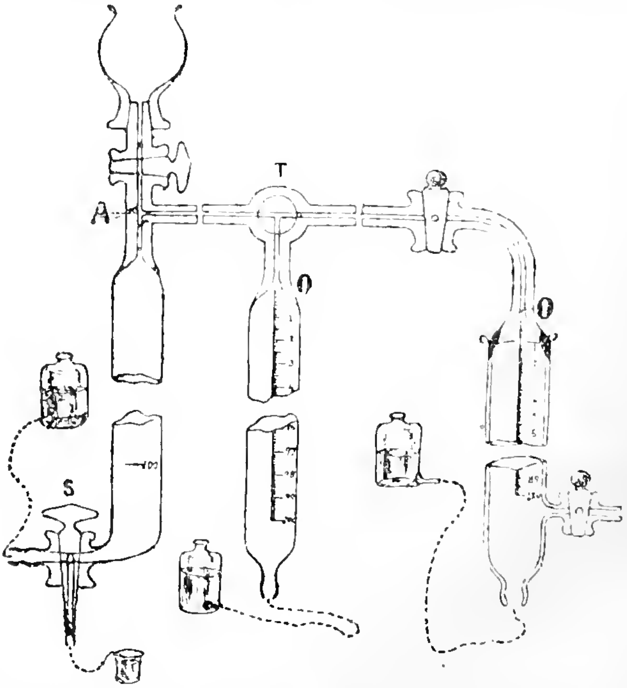
of solution, and from his results has calculated the necessary tables in regard to the change in specific rotation.—C. A. K.

---

*An Improved Form of Elliot's Gas Apparatus.** J. B. Mackintosh. Amer. Chem. J. 9, 294—296.

A THREE-WAY T-stop-cock is attached to the measuring burette whereby connection can be made between any two of the burettes at will. In the measuring and explosion burettes the zero point O is taken at that point where the capillary tube expands into the burette. Water will remain in the capillary tube when the excess flows to the bottom of the burette and thus the adjustment to zero is rendered automatic. The absorption tube has a single graduation at 100cc. measured from A. Any gas remaining in the portion above A can be expelled by forcing water out of one of the other burettes, the cock S being closed.

In transferring gas from the measuring tube to the explosion burette its complete removal from the capillary tube is effected by passing water from the absorption tube or by letting it flow in from the funnel. This done, the stop-cock T is turned so as to connect the explosion and absorption tubes, while the measuring tube is completely shut off. The oxygen or air for the explosion can be admitted through the lower stop-cock of the explosion burette or through the funnel of the absorption tube. A supply of oxygen may be generated in the absorption vessel from potassium permanganate and hydrogen peroxide. After mixing the gases in the explosion tube, the explosion is made, the correction noted, the gas transferred to the absorption burette and finally re-transferred to the explosion burette and measured.—C. A. K.



Detection of Metals by Electrolysis. Mayencon. Journ. de Phys. Elément, 1887, 172.

THE gold in a solution containing 1 part in 1,000,000, and made by dissolving 0·005grm. of gold in aqua regia, and diluting the solution to 5 litres with water (acidified with sulphuric acid) may be detected in less than a minute by electrolytic deposition on a wire.—C. A. K.

The Application of Ammonium Dithiocarbamate in Analysis. J. Klein. Rep. Anal. Chem. 7, 629—639 and 645—654.

FOR the preparation of ammonium dithiocarbamate free from sulphocarbonate Mulder's directions (*J. Prakt. Chem.* 103, 178) are adopted, the ammonium generated from 150 parts of ammonium chloride and 300 parts of quicklime being passed into 600 parts of 95 per cent. alcohol, and there treated with 95 parts of carbon bisulphide. At 30° almost pure dithiocarbamate crystallises out, which is filtered, washed with alcohol, and dried between filter paper—$CS_2 + 2NH_3 = CS(NH_2)SH.NH_3$. The presence of any sulphocarbonate of ammonium is evident by its turning red on exposure to the air; it can thus be mechanically removed if present. If a very little of a solution of a sulphocarbonate be added to one of nickel sulphate which has been treated with an excess of ammonia and strongly diluted, a red zone is formed at the point of contact of the two liquids, and on shaking the whole solution becomes red. In this way the purity of the ammonium dithiocarbamate used in the following experiments was always tested.

In all cases a 5 per cent. aqueous solution of ammonium dithiocarbamate was used; it is advisable to keep a solution for use in preference to the solid, the latter being more liable to decompose after being kept for some time.

Determination of Copper.—A solution of copper sulphate treated with ammonium dithiocarbamate yields a yellow precipitate of copper dithiocarbamate—$Cu.(CS.NH_2.S)_2$. It the precipitation is effected in the boiling solution, the precipitate settles well and can be readily filtered. It dissolves in much hydrochloric acid after prolonged boiling and gradually becomes dark coloured, while ammonia and caustic soda darken the precipitate at once. It dissolves readily in nitric acid on warming, and is unaffected by water or long exposure to the air. Heated with sulphur in a current of hydrogen cuprous sulphide (Cu_2S) remains. For the quantitative determination of copper by this reaction, the solution (in absence of other metals) is acidified with a little hydrochloric acid, heated to boiling, and an excess of the 5 per cent. solution of ammonium dithiocarbamate added, the boiling is continued for 10—20 seconds, the precipitate allowed to settle, filtered, washed on the filter with hot water and dried. It is finally

---

* See Chem. News, 1883, October.

ignited with sulphur in a current of hydrogen and the cuprous sulphide weighed. Results by this method agree closely with those obtained by precipitating the copper solution with sulphuretted hydrogen and weighing as cuprous sulphide directly. Copper in silver coins can be thus determined, the silver being first removed as chloride. (This, provided silver and copper only present.)

Determination of Zinc.—Zinc sulphate is precipitated by ammonium dithiocarbamate as a white precipitate, soluble in excess, and reprecipitated on boiling. Zinc dithiocarbamate is soluble in nitric and hydrochloric acids, insoluble in dilute acetic acid. In the quantitative determination sodium acetate and acetic acid are added to the solution of zinc sulphate: the solution is heated to boiling, ammonium dithiocarbamate added, and the boiling continued for a short time, when the precipitate is allowed to settle, filtered hot, washed, etc., and finally weighed as zinc sulphide, as in the previous instance. In the filtrations the filtrate is apt to be slightly turbid, but the quantity of zinc passing through is so small that it may be disregarded.

Separation of Copper and Zinc.—This depends on the solubility of zinc dithiocarbamate in hydrochloric acid. Hydrochloric acid (sp. gr. 1·05) is added to the mixture, which is then heated to boiling and precipitated with ammonium dithiocarbamate. The precipitated copper retains a small quantity of zinc and should be redissolved in nitric acid, evaporated down with hydrochloric acid and reprecipitated. The combined filtrates contain the zinc, which can be precipitated as dithiocarbamate, in acetic acid solution. An analysis of the mixed sulphates of copper and zinc, also an analysis of brass, gave accurate results by this method.

Separation of Copper from other Metals.—Copper is completely separated from iron, manganese and nickel by precipitation in the hot hydrochloric acid solution with ammonium dithiocarbamate. Cobalt solutions turn green when thus treated, and it is only after prolonged boiling that they become red again, and the separation does not appear to be quite complete under all conditions. Copper (and also zinc) is completely separated from the metals of the alkalis and alkaline earths, provided the solution is sufficiently dilute.

Action of Ammonium Dithiocarbamate on :—

1. *Salts of Aluminium and Chromium.*—In the cold no reaction occurs, but on warming sulphuretted hydrogen is evolved, and the hydrates separate. In the case of chromium small blue crystals, insoluble in cold hydrochloric acid, and consisting probably of chromium dithiocarbamate, were observed. Chromates are reduced by this reagent as by sulphuretted hydrogen.

2. *Salts of Iron, Nickel, Cobalt, Manganese, Zinc and Uranium.*—Ferric salts are reduced, while ferrous salts are not affected in the acid solution: an addition of ammonia causes the separation of a dark precipitate. Nickel and cobalt are not completely precipitated either in acid or alkaline solution. Manganese is only precipitated in alkaline solution, while the zinc precipitate is insoluble in acetic acid (v. *ante*). The separation of zinc and manganese on this basis does not work. Nickel, cobalt, and zinc treated with an excess of potassium cyanide are not precipitated by the dithiocarbamate. Uranium solutions are coloured red in the cold (*Debus. Annalen*, **73**, 26); on boiling a grey-black precipitate settles, insoluble in acetic acid solution, soluble in hydrochloric. The red coloration is destroyed by the presence of ammonium carbonate.

3. *Salts of Mercury, Lead, Silver, Bismuth, Copper and Cadmium.* (See *Debus. l.c.*).—With mercuric chloride a white, and with mercurous nitrate a black, metallic precipitate is formed. The precipitates with lead and silver are pale yellow, that with bismuth orange-yellow, and that with cadmium white. They are all more or less rapidly decomposed on boiling with water, and almost immediately by alkalis. The solutions of these metals treated with an excess of potassium cyanide are not precipitated. The bismuth and cadmium precipitates are fairly soluble in hydrochloric acid, the copper salt (v. *ante*) highly soluble, the lead salt readily so.

4. *Oxides of Arsenic, Antimony and Tin.* (See *Debus. l.c.*).—Mixed with an aqueous solution of arsenious acid, a yellow precipitate, probably, of sulphide of arsenic separates on standing. In presence of hydrochloric, sulphuric or acetic acid a white flocculent precipitate results, soluble in alkalis and reprecipitated by acids. The precipitate liberates no ammonia when boiled with caustic soda, but if it be first boiled with water and then with caustic soda ammonia is liberated, and on the addition of acid, fumes of sulphocyanic acid are given off. Arsenic acid is similarly precipitated in acid solutions. Antimony trichloride forms a pale yellow precipitate, which behaves similarly to the above, while antimony pentachloride also yields a pale yellow precipitate soluble in alkalis, but decomposed on boiling the solution. Stannous chloride in acid solution forms an orange-yellow precipitate, soluble in alkalis, reprecipitated by acids and decomposed on boiling with evolution of carbon dioxide and sulphuretted hydrogen. Stannic chloride behaves similarly, but the precipitate is yellow.
—C. A. K.

Laboratory Apparatus. E. Pollak. Rep. Anal. Chem. **7**, 597—599.

Fig. 1 represents a piece of apparatus specially adapted for chlorinations, since the separate portions are joined together by ground glass connections. The neck of the flask is fitted with a short tube open at both ends, into the side of which the delivery tube for the gas is fixed; this last is expanded at the bottom and contains several small holes. The upper portion of the short tube is fitted to the outside of a condenser, which, as shown in the figure, is cooled from the inside. Fig. 2 is a similar form of condenser, cooled from the inside, to be used for extractions. The exsiccator (Fig. 3) is provided with a manometer, to which the exit tube is attached. A cock is provided at the bottom of the exsiccator.—C. A. K.

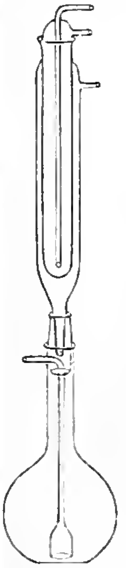


Fig. 1.

Fig. 2.

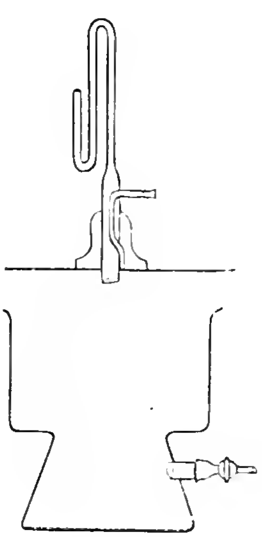

Fig. 3.

Action of Hydrogen Arsenide on Arsenious Anhydride dissolved in Hydrochloric or Sulphuric Acid. D. Tivoli. Rend. R. Acc. Sc. d. 1st Bologna, 1887, 98.

Arsenious anhydride dissolved in water yields no metallic arsenic when treated with hydrogen arsenide, but in presence of hydrochloric or sulphuric acid the following reactions take place:—

$$2AsH_3 + 2AsCl_3 = 6HCl + As_4.$$

$$6AsH_3 + 3(As_2O_2)SO_4 + H_2SO_4 = 4H_2SO_4 + 6H_2O + 3As_4.$$

The reaction is complete in the former instance, and nearly so in the latter.—C. A. K.

New Apparatus for Fractional Distillation. U. Gayon. Ann. Chim. Phys. 1887, 555.

THE author has made use of this apparatus for distilling off the alcohol from fermented solutions. A is the distilling flask, holding 3—4 litres, which is heated in a calcium chloride bath M, or better, by means of steam generated from the autoclave O, to which the cock *r* is attached. To prevent the augmentation of the volume of the liquid in A by the condensed steam the flask is surrounded by a water bath; M is a water manometer. The fractionating column consists of a series of glass tubes separated from one another by metal plates P (Figs. 2 and 3). The tubes are supported by iron rods T fixed in the metal plates at *t* (Fig. 3). The plates are open in the centre and are covered by pieces of tinned or silvered-copper foil full of numerous small holes of 1mm. diameter. The tube G holding the reversed glass siphon S is fixed as shown in Fig. 2. E is a small piece of tin foil, and C a piece of indiarubber. The longer limb of the siphon contains a small hole at O to allow the liquid condensed above the plate to run down to the next lower division of the dephlegmator. At the top of the apparatus the tube C (Fig. 1) is fixed, and inside it the tube D, which is connected with a vertical condenser at A (not shown in figure). In D a liquid of constant boiling point is placed and also some platinum wire to render the boiling regular. By this means a constant temperature is maintained at the top of the column. The tube C is connected with the exit tube T, in which the thermometer is fixed and from which a second tube branches off leading to the condenser. When in use the glass siphons soon become filled with the less volatile portions of the liquid distilled, causing the vapours to pass through the small holes of the plate O (Figs. 2 and 3). With a column consisting of 12 plates and with pure alcohol in the analyser D, the strength of the alcohol distilled from wine or other fermented liquids is 94—95 per cent.—C. A. K.

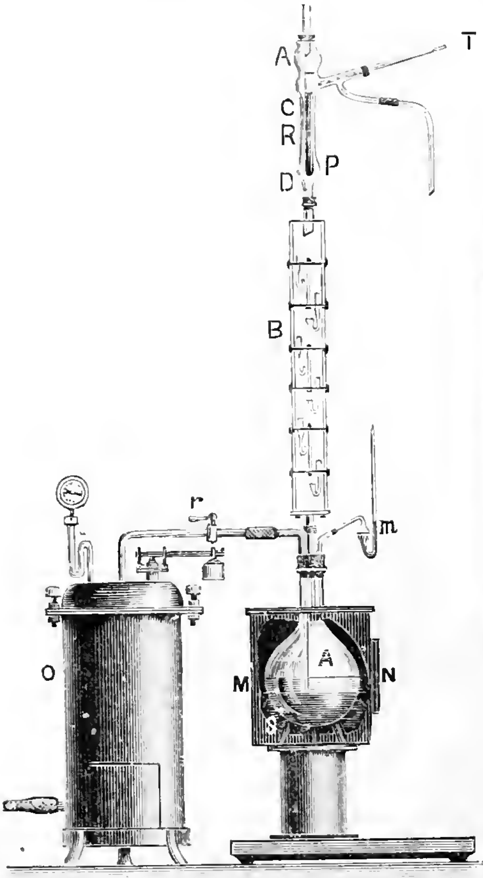

FIG. 1.

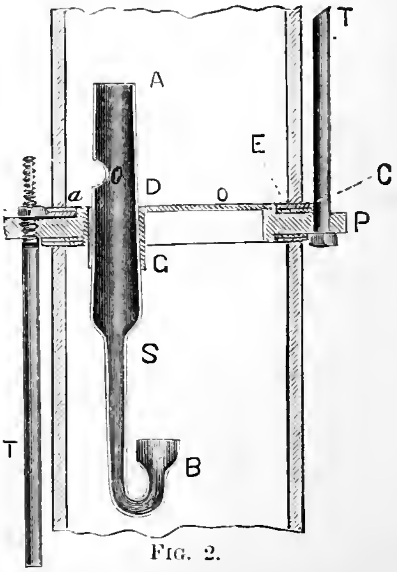

FIG. 2.

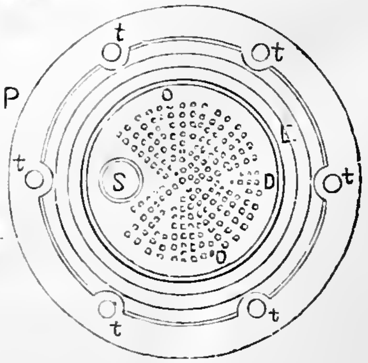

FIG. 3.

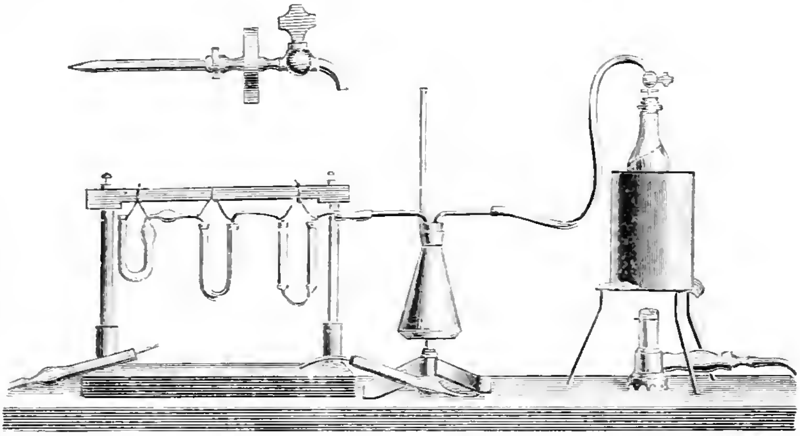
New Method for the Quantitative Determination of Phosphoric Acid in Thomas-slag. J. H. Vogel. Rep. Anal. Chem. **7**, 568—573.

0·5GRM. of the well-sampled slag is heated with 50cc. on dilute hydrochloric acid (sp. gr. 1·030—1·025) for 24 hours in a beaker with occasional stirring. With the exception of carbon and a little gelatinous silica everything goes into solution; this residue is filtered off and washed with 50—60cc. of the dilute acid. The filtrate is evaporated to dryness in a porcelain or platinum crucible and dried at 108—110° for half-an-hour. When cold the residue is treated with 10cc. of conc. nitric acid, and then with 20—25cc. of hot water. All but the last traces of silica are thus got rid of, and the determination of the phosphoric acid consequently rendered more accurate, the presence of silica, according to the author, involving low results. The small quantity of silica left in the solution is without effect, provided the molybdic acid precipitate is thoroughly washed. The silica, after the treatment with nitric acid, is filtered off and the phosphoric acid precipitated by ammonium molybdate as usual. Thomas-slag is similarly decomposed by other dilute acids (nitric and sulphuric), although hardly so effectually as by hydrochloric acid. The results obtained by the above method are slightly higher than when no removal of silica is effected, or when Brunnemann's method (see this Journal, 1887, 304) or the method proposed by the author, of treating the slag with a mixture of hydrochloric and nitric acids (see this Journal, 1887, 679) is employed.—C. A. K.

The Estimation of Carbonic Acid in Beer. C. A. Crampton and T. C. Trescot. Amer. Chem. J. 9, 290—293.

THE method applies only to bottled beer. The carbon dioxide is allowed to escape from the bottle by boring through the cork with a champagne tap, the thread of which has been turned off and the tube left smooth (see figure), and passes first through an Erlenmeyer's flask and then through U-tubes containing sulphuric acid, calcium chloride and soda lime successively, the whole being arranged as shown in figure. The Erlenmeyer's flask serves both to catch and to break up the froth coming over from the bottle. Towards the end of the operation the contents of the bottle are warmed to 80° and finally a current of air (freed from CO_2) is drawn through the system of U-tubes. With patent rubber-stoppered beer bottles the carbon dioxide cannot be determined in this manner and the method of total loss is adopted, the bottle, together with the drying tubes, connections, etc., being weighed before and after the determination. The authors find as a mean of 16 results 0·398 per cent. of CO_2, the quantities varying from 0·219 per cent. to 0·629 per cent. Most authorities give an average of 0·1 to 0·2 per cent. of CO_2 in beer.—C. A. K.



On Sulphurous Acid and Iodometry. J. Volhard. Annalen, 242, 93—113.

BUNSEN explains the well-known fact, that in his iodometric method the sulphurous acid is not completely oxidised to sulphuric acid unless the sulphurous acid solution is very dilute—(*i.e.*, 0·03—0·04 per cent. sulphur dioxide), by the supposition that in a more concentrated solution the sulphuric acid first formed is again reduced by the hydriodic acid. Now this explanation, though it has never been experimentally proved, has been universally accepted and is often cited as an instance of a reversable reaction. The author has carried out numerous experiments on the subject, with the following results:—(1.) The presence of even 10 per cent. of sulphuric acid does not influence the correctness of the results. The reduction of *sulphuric acid* is not therefore the cause of irregularities when strong solutions are used. (2.) When the iodine solution is run into the sulphurous acid solutions, the results are never so concordant (even with a 0·0153 per cent. solution; factor of iodine solution = 0·1013) as when the sulphurous acid solution is run into the iodine solution, when concordant results are obtained, even with a 2 per cent. solution of sulphurous acid. The necessity of an excess of the oxidising agent at the commencement of the experiment is therefore apparent. (3.) The supposition that possibly a portion of the sulphurous acid is converted into dithionic acid ($2SO_3H_2 + 2I = S_2O_6H_2 + 2HI$) was not borne out by experiment. The correct explanation can therefore alone be based on the following observations:—(1.) Sulphur dioxide is reduced by hydriodic acid: iodine, water, and sulphur (and a little hydrogen sulphide) being formed. (2.) A solution of hydriodic acid similarly reduces a concentrated solution of sulphurous acid. The iodine is not, however, liberated, but in presence of the water at once oxidises a further portion of sulphurous acid to sulphuric acid. The final result of the reaction is therefore a conversion of the sulphurous acid into sulphur and sulphuric acid:—$3SO_2 + 2H_2O + 4HI = 2SO_4H_2 + S + 4HI$. The ratio of sulphur, as sulphuric acid, to free sulphur was proved quantitatively. We here have a very neat example of so-called catalytic action. Now when iodine and sulphurous acid solution are mixed, hydriodic acid is formed, and this may cause a further reduction of a further portion of the sulphurous acid. This is of course more liable to occur, even when dilute solutions are used, when the iodine solution is run into the sulphurous acid solution than when the reverse takes place. It is interesting to note here that the prolonged action of alkaline sulphites exerts a similar action on sulphurous acid: sulphur and sulphuric acid being formed, hydro-sulphurous acid being formed as an intermediate product. When concentrated solutions are used, not a colourless solution, but a slightly yellow one, is obtained, which does not turn starch blue; the colour is therefore not due to free iodine.—F. W. T. K.

Examination of Crude Soda-liquors and Mother-liquors. W. Kalmann and J. Spüller. Dingl. Polyt. J. 264, 456—459.

THE authors propose to determine the composition of crude soda- and mother-liquors in the following manner, instead of by the method at present in use. The separation of the Na_2SO_3 from $Na_2S_2O_3$ by the author's method depends on the almost complete insolubility of $BaSO_3$ in alkaline liquids, whilst BaS_2O_3, in the state of dilution dealt with, remains in solution. Experiments carried out with solutions of known composition showed that only a very slight, negligable amount of BaS_2O_3 remained in the precipitate. The method of procedure is shortly as follows.

1. In a measured volume of the liquor the total alkali is determined with normal acid and methyl-orange as indicator. The amount of acid used corresponds to the amount of sodium carbonate + sodium sulphide + sodium hydroxide + half the sodium sulphite. (Methyl-orange is alkaline to Na_2SO_3, neutral to $NaHSO_3$.)

2. An equal volume of the liquor is titrated with a decinormal iodine solution, after acidification with acetic acid and addition of starch-paste. The iodine used corresponds to the amount of sodium sulphide + sodium sulphite + sodium hyposulphite.

3. Twice the volume of the liquor employed in (1) and (2) is precipitated with alkaline zinc solution, the liquid made up to a certain volume, one-half filtered off, acidified with acetic acid and titrated with decinormal iodine solution and starch paste. The iodine used corresponds to the sodium sulphite + sodium hyposulphite.

4. Three or four times the volume of the liquor taken in (1) and (2) is decomposed with barium chloride in excess, made up to a given volume with boiled water, and the precipitate filtered off; *a*, one-third or a quarter is titrated with normal acid. The acid used corresponds to sodium hydroxide + sodium sulphide; (*b*) another third or quarter of the filtrate is acidified with acetic acid and titrated with decinormal iodine solution. The iodine used corresponds to the sodium sulphide + sodium hyposulphite.

The calculation then is:—

$2 - 4b$ = A cc. of decinormal iodine solution corresponding to Na_2SO_3.

$2 - 3$ = B cc. of decinormal iodine solution corresponding to Na_2S.

$4b - (2 - 3)$ = C cc. of decinormal iodine solution corresponding to $Na_2S_2O_3$.

$4a - \frac{1}{10}B$ = D cc. of decinormal acid corresponding to NaHO.

$1 - (4a + \frac{1}{20}A)$ = E cc of decinormal acid corresponding to Na_2CO_3.

The numbers are then calculated on the litre of liquor. Analyses are given, showing the fairly concordant results obtained by the method, which answers well for all practical purposes. (Compare *Dingl. Polyt. J.* **237**, 308.)—G. H. M.

Liebermann's Reaction for Albumen. C. le Nobel. Centralbl. f. die Med. Wissensch. **25**, 625.

THE author confirms the accuracy of Liebermann's results (*Chem. Zeit. Rep.* **11**, 130. With a sample of pure peptone prepared from fibrin according to Kühne's method and which was not precipitated by either acids, alkalis, ammonium sulphate, or acetic acid and neutral alkaline salts, and which gave the red coloration with the biuret test, the reaction with hydrochloric acid gave no result. Whether the presence of albumen in urine can be detected by this test cannot be stated with certainty, but in one case in which it was present by the microscope and all the usual albumen reactions failed, this test answered extremely well.

The author has further succeeded in detecting globulin in urine by saturating a large quantity of the former with magnesium sulphate.—C. A. K.

Detection of Woody Fibre in Paper. E. Hanansek. Ztschr. f. Nahrungmittelrentersuch u. Hygiene, 1887, **1**, 153.

THE author examined several varieties of wood cellulose which did not give the usual colour reactions with aniline or phleroglucinol, and considers, therefore, that in order to detect woody fibre in paper both a microscopical and chemical examination should be made.
—C. A. K.

Separation of the Opium Alkaloids. P. C. Plugge. The Analyst, **13**, 197—200.

To the solution of the free alkaloids add sodium acetate.

(*a*) Precipitate: Narcotine and papaverine.

(*b*) Filtrate: Narceine, thebaine, codeine, and morphine.

(*a*) Dissolve in least possible quantity of HCl and dilute the solution so that 100cc. contains only 0·25grms. of alkaloids, and precipitate with K_3FeCy_6; precipitate is papaverine hydroferrocyanate, which may be weighed as such. Filtrate contains the narcotine, which can be obtained as pure alkaloid by addition of ammonia.

(*b*) Filtrate (from sodium acetate precipitate) concentrate on the water bath to small volume when the narceine crystallises out, only 0·16grm. remaining in 100cc.

(*c*) Filtrate contains thebaine, codeine, and morphine. Add concentrated sodium salicylate solution and allow to stand for 24 hours.

(*d*) Precipitate: Thebaine salicylate; weighed as such.

(*e*) Filtrate: Add HCl. The excess of salicylic acid is precipitated and may be filtered off, and the filtrate is shaken out with chloroform, which removes traces of salicylic acid, narceine, and thebaine.

(*f*) The solution, after extraction with chloroform, contains the codeine and morphine. Concentrate on water-bath, and add potassic sulphocyanate.

(*g*) Precipitate: Codeine hydrosulphocyanate, weighed as such.

(*h*) Filtrate contains morphine and a little codeine, which has escaped precipitation. Add a little ammonia, allow to stand for some time in a separating funnel and shake out repeatedly with chloroform, which removes the last traces of codeine. Separate the aqueous solution, acidify with HCl, heat to about 60° C., render alkaline with NH_3 and shake out the morphine with amyl alcohol.

The experimental results given are very satisfactory.
—J. W. L.

Detection and Direct Estimation of Starch in Solutions containing Dextrin. G. Burkhard. Chem. Zeit. **11**, 1158.

THE qualitative test for starch in presence of dextrin is to add alcohol to the cold solution until it just becomes turbid, when the solution is warmed until the turbidity disappears. The starch is then precipitated by tannic acid solution, filtered off, washed with alcohol, dried and tested for on the filter paper with a dilute iodine solution. In applying this method of separation to the quantitative estimation of starch the precipitation is similarly effected, the tannic acid completely removed by washing with alcohol, and the residue (filter paper and starch) heated with 1cc. of normal sulphuric acid and 20cc. of water for 4 hours to 115° C. in a paraffin bath. After the heating (which is done in a Lintner's pressure flask), the solution is filtered and the sugar formed determined by Fehling's solution. The quantity of sugar found, multiplied by 0·9, gives the amount of starch. Allihn's table for reckoning the quantity of copper solution used should be employed.—C. A. K.

Determination of Ash in Organic Substances. A. Köbrick. Chem. Zeit. **11**, 1159.

5—10GRMS. of substance are heated in a platinum dish to begin with, as the loss is less than when a platinum crucible is used, the tendency of the substance after being first ignited to creep over the sides of the vessel being reduced. If the sample examined be readily burned, the ignition is completed in the dish; if not, the residue is broken up, transferred to a platinum crucible, and heated in a current of oxygen. The oxygen is passed into the crucible by a pipe-clay tube (such as is used for the reduction of a metallic oxide in a crucible) and may be generated for the purpose from potassium chromate and sulphuric acid or from potassium permanganate and nitric acid, the gas being washed with water. The organic matter is burned away completely and quietly, so that there is no chance of loss by spirting. Any particles of carbon remaining in the ash, in case it is fusible, are removed by exhausting with water and concentrating carefully, when the light carbon particles remain on the surface and are readily oxidised.—C. A. K.

Notes on the Soda-Lime Method for Determining Nitrogen. W. Atwater and C. Woods. Amer. Chem. J. **9**, 311—324.

FROM a series of determinations of the nitrogen contained in animal tissues, the authors consider the soda-lime method quite reliable, results by this method agreeing accurately with those obtained by the volumetric process. The composition of the soda lime is without appreciable effect on the results; nor does a difference in the temperature of combustion, or of the length of the tube, affect the accuracy of the method. In testing the purity of the soda lime by sugar it was found to contain traces of nitrogen, while, when burnt with stearin or oxalic acid, it appeared quite free from it, the traces of nitrogen being, therefore, in the sugar, which it is advisable to replace for this purpose by the above substances.—C. A. K.

Testing of Commercial Quinine Sulphate. G. Kerner and A. Weller. Arch. Pharm. 1887, 712 and 749.

THE authors give the following directions for the ammonia test:—Allow the sample to effloresce completely in a warm place (40—50° C.), and then treat 2grms. with 20grms. of water in a suitable test tube. Heat the tube for half-an-hour in a water-bath to 60—65°, and afterwards allow it to cool for two hours in a water-bath at 15°. Both during the heating and cooling it is necessary to shake the contents of the tube well from time to time. Next filter the solution, take 5cc. of the filtrate and add to it ammonia of specific gravity 0·960. It is important that the temperature of the cooling bath should be as nearly as possible exactly 15° before filtering. The ammonia is added until the precipitate first formed is just dissolved. Pure quinine sulphate requires 3·4—3·5cc. of ammonia; when mixed with 3 per cent. of pure cinchonidine sulphate, 4cc. of ammonia are needed, and with 7 per cent. about 6cc. In the better classes of commercial quinine sulphate the quantity of cinchonidine sulphate at present is 2—6 per cent.

The authors contend that thus modified the ammonia method is the safest and simplest known for the detection and estimation of admixed alkaloids in quinine sulphate. Hesse's ether test, which differs from the above by the substitution of ether for ammonia, for cinchonidine, takes longer and depends too much on the quality of the ether employed.

De Vrij's chromate method (see this Journal, 1887, 151, 306, and 388) is open to the objections that pure quinine sulphate is not completely precipitated as chromate, and that the quantity of the precipitate, obtained by the addition of alkali to the filtrate, is not appreciably different with pure quinine or when 2—2·5 per cent. of cinchonidine is present; also less than 3·5 per cent. of quinidine cannot be detected. In Schäfer's oxalate method (see this Journal, 1887, 522) a portion of the cinchonidine remains behind with the quinine oxalate, while varying quantities of quinine pass into the filtrate. The bisulphate method (see this Journal, 1887, 455) is of use in the removal of cinchonidine in the preparation of quinine, but as a test it is unreliable, as the cinchonidine is not completely precipitated from the ethereal solution, and then it has to stand for 24 hours.

These criticisms, which are based on numerous analyses, show that the chromate and oxalate tests can only determine whether, in the sample examined, a certain small percentage of cinchonidine is exceeded or not.
—C. A. K.

Gypsum and Calcium Sulphide in Bone Charcoal. Ztschr. f. Zuckerind. 1887, 704.

IF, in determining the calcium sulphide in bone charcoal, the moist sample be dried at or about 100°, a portion of the sulphide is oxidised to sulphate, owing to the formation of hydrogen peroxide. The charcoal is therefore best dried at the ordinary temperature, and treated with hydrochloric acid after the addition of zinc (to reduce the ferric oxide), and the sulphuretted hydrogen absorbed in an ammoniacal silver solution, the silver sulphide formed being either weighed directly or else as metallic silver by reduction in a current of hydrogen. A better plan is to dissolve the sulphide in nitric acid, and titrate the solution with ammonium sulphocyanide, according to Volhard's method. With 20grms. of substance the results only differ by 0·003—0·005 per cent. The removal of gypsum from bone charcoal, by means of sodium carbonate, is best effected by using one mol. of the latter for each mol. of calcium sulphate, and is the more readily done the higher the temperature. Digestion for four days is sufficient, for, although the extraction is only completed after 15 days at ordinary temperatures, after the fourth day the quantity of calcium sulphide gradually increases, owing to the reduction of the gypsum in solution by bacteria (Beggiota alba ?). Washing with dilute hydrochloric acid does not appreciably diminish the amount of calcium sulphide present in the charcoal, but bringing the moistened substance in contact with air does, owing to the oxidation by hydrogen peroxide.—C. A. K.

Examination of Gun Cotton. Dingl. Polyt. J. **265**, 332.

IN a recent communication Wisser gives the results of experiments on the chemical examination of gun cotton. Moisture and calcium carbonate were determined in the usual way. The ash was found, after removal of the calcium carbonate, by treating a weighed quantity in a tared platinum crucible with concentrated nitric acid, carefully evaporating to dryness and igniting the residue; the increase of weight gives the ash. The nitrogen was determined with a Lubarsch's nitrometer. Mono- and di-nitrocellulose were found, when 5grms. of the cotton wool were treated first with 200grms. of a mixture of ether and alcohol in the ratio of 3 : 1 for 12 hours; then, with the same amount in the ratio of 2 : 1 for six hours, and finally with the same amount of 1 : 1. After standing some time the liquid was poured off through a tared filter, the residue washed twice with pure alcohol, twice with dilute alcohol, and then several times with water: it was then collected on the filter, dried at 60°, and weighed; the loss of weight gave the lower nitro-bodies. For the determination of the unnitrated cellulose a weighted quantity of the gun-cotton was boiled for 15 minutes in a concentrated solution of sodium stannate, which dissolves out the nitrated cellulose; the residue is filtered off, washed, dried at 100°, and weighed. The tin salt must be freshly prepared each time by melting caustic soda with tin and dissolving the product.—G. H. M.

Detection of the Adulteration of Olive Oil with Vaselin Oil. J. Birl. Archiv der Pharmacie, **225**, 310.

LATELY the fat oils have been much adulterated with vaselin oil; olive oil has also suffered in this respect, and is consequently unfitted for pharmaceutical purposes, since the oil adulterated in this way gives neither a proper plaster, soap, nor liniment. The author has now devised a new method for detecting vaselin oil in vegetable oil, which promises to be very useful. He tests the vegetable oil for mineral oil by titration with standard alcoholic potash. 65grms. of the purest potash are dissolved in 1 litre of 95 per cent. alcohol, and the solution made of such a strength that 10cc. are neutralised by 10cc. of normal sulphuric acid; this solution will keep well. 10grms. of the oil to be examined are heated to boiling for 10 minutes in a porcelain dish with 40cc. of the potash solution; water is then added until the volume is 100cc. The mixture is again warmed with shaking, whereby the soap formed goes into solution, and titrated with normal acid in the ordinary way, using phenolphthalein as an indicator. Pure oils require 6cc. of acid (with the exception of castor oil and the oils from the *Cruciferæ*, which require 7—8cc.), vegetable oil with 10 per cent. of mineral oil requires 8cc., with 20 per cent of vaselin oil 11cc.; the adulterated oils of commerce, examined by the author, required 14 to 17cc. of normal sulphuric acid. (Compare Focke, this Journal, 1886, 176.)—G. H. M.

Trade Report.

(From the Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Customs Decisions.

(Poud = 36lb. avoirdupois. Gold rouble = 3s. 2d.)

The following decisions affecting the classification of articles in the Russian Customs Tariff have recently been given by the Russian Government.

Ozokerite, not bearing traces of chemical purification by means of sulphuric acid.—Section 16. Duty, 5 copecks per poud gross, with an addition of 20 per cent. on each rouble of duty leviable.

Ozokerite chemically purified with sulphuric acid.—Section 26, Part 6. Duty from 30 copecks to 1 rouble per poud, with an addition of 20 per cent. on each rouble of duty leviable.

Essences containing spirit.—Section 77. Duty, 75 copecks per bottle.

Starch paste, with an admixture of chloric zinc.—Section 45. Duty, 1 rouble per poud, with an addition of 20 per cent. on each rouble of duty leviable.

Pigment of coal tar.—Section 120. Duty, 15 roubles per poud.

Dry paper pulp, impregnated with coal tar.—Section 140. Duty, 2 roubles per poud, with an addition of 20 per cent. on each rouble of duty leviable.

SPAIN.

Regulations respecting the Importation of Alcoholic Liquors.

See *Board of Trade Journal* for December, p. 596.

UNITED STATES.

Customs Decisions.

Thymol or thymic acid, an article not enumerated by name in the existing Tariff Acts, upon investigation, is found to be commercially known as an acid, and to be used chiefly for medicinal purposes, both externally and internally, and it is therefore held that it is entitled to free entry, under the provision in the free list, No. 594, for "acids used for medicinal purposes, not specially enumerated or provided for."

Certain so-called "wool grease," which upon investigation is found to consist of an expressed oil of wool, commercially known as solid fat oil of animal origin, is held to be dutiable at the rate of 25 per cent. *ad valorem*, under the provision in section 92, for all "preparations known as expressed oils."

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

Industrial and Commercial Museum at Lisbon.

See *Board of Trade Journal* for December, p. 638.

Dutch Colonies.

Java Indigo.

The indigo crop of 1886 was satisfactory, both as regards quality and quantity. During the year 612,000kilos. were exported from Batavia, against 601,000kilos. in 1885, and an average export of 122,000kilos. from 1880 to 1884. The high prices which ruled at the commencement of 1886 could not be maintained, and the season closed at decidedly lower rates than the one preceding. Prices, in fact, were so low that the planters would not sell outright, but preferred to ship the bulk of the crop to Holland for their own account. The finest varieties are becoming more and more scarce. The 1887 crop does not look favourable as regards quantity, having suffered from excessive rains and insects.

Tunis.

Condition of the Country.

In a country which, like Tunis, depends for its commercial prosperity on the productions of the soil, there is little change from year to year in the totals of its exports and imports, unless a year of drought should cause a failure of the crops. Such a calamity has not befallen the land since France took it under her protection in 1881. In spite, however, of the continuance of agricultural prosperity, the trade of Tunis languishes. commercial failures are of unusual frequency, and small merchants find it increasingly difficult to obtain credit.

British Trade.

England continues to occupy the first place in the imports. Her pre-eminence is due to the cheapness and excellence of the products of Manchester and Glasgow. What is chiefly needed to give a stimulus to British import trade is the establishment of direct steam communication with Liverpool, which would permit of the introduction of British goods at cheaper freights. English commercial firms might then hope to sell in Tunis many articles which are at present hardly known in the Regency.

The Cork Forests.

The forests of Tunis cover an appreciable part of the surface of the country, and their care has been placed under the management of a separate department by the French. The explorations of the new department have resulted in the division of the forests into two main groups; one consisting of the cork tree and deciduous oak, locally known as "Zen," covering the north-western angle of Tunis where it abuts on the Algerian frontier and the sea, inhabited by the Kroumirs, and separated from the rest of Tunis by the river Mejerdah. These trees grow in a stratum of sandstone, which again reposes on the upper chalk, and they completely disappear where the latter stratum crops to the surface. They cover an area of about 360,000 acres, on 330,000 acres of which flourishes the cork tree, and on 30,000 the "zen." It is found that the former invariably grow on the southern slopes of the mountains; the latter on the northern slopes, and in the hollows of valleys.

Red Gum Trees.

The French railway company which owns the line running from Tunis to the Algerian frontier, has succeeded in planting a considerable number of the *eucalyptus resinifera* (red gum trees) and *acacia cyanophyla*. It is estimated that 300,000 trees have been planted along the line of railway. The cost of planting an acre with the eucalyptus amounts to £20, about 1,600 trees going to the acre of nursery ground. After planting out, it is probable that at the end of twenty years 600 trees will have survived, worth 8s. apiece. The bark of the *acacia cyanophylla* is rich in tannin, and valuable for the tanner.

Saleable Drugs and Chemicals.

The total value of drugs and chemicals imported during 1886 was £25,643, but there are no detailed figures given of the imports from the different nations trading with Tunis, and only this much can be said with certainty, that in the general imports, Great Britain occupies the first, and France the second place. The Germans have made many unavailing efforts to gain a footing in the drug and chemical line. There is scarcely any industry extant in Tunis in which chemical products can find employment, and the consumption is, therefore, limited to a few articles only. Painters' colours, ultramarine (but only the cheapest qualities, powdered and in ball form), indigo, and incense, are the only articles which are employed largely, and which it will pay to import direct. Most other goods are taken in small quantities, and can only be imported economically assorted with other goods. The same is the case with pharmaceutical articles. The laboratories of the Tunisian pharmacies are generally of a very primitive character, and, wherever possible, the pharmacist prefers to buy the preparations put up ready for sale. Manufacturing firms and wholesalers who sell crude products only have, therefore, little chance of doing a large trade, but not so firms who, in addition to quinine, iodine, magnesia, etc., also offer specialities, such as mustard plasters, fluid preparations, and patent medicines of all varieties.

Hayti (San Domingo).

Logwood.

The logwood trade has been much depressed lately, mainly in consequence of excessive competition. There is a very good demand—larger, in fact, than the supply—for the better varieties of logwood. In consequence a good deal of inferior wood is brought down from the interior, and these shipments give rise to claims on the part of the receivers in Europe. The exports from Hayti fell from 293,518,750lb. in 1885 to 273,526,277lb. in 1886. The decrease is principally owing to reckless destruction of the woods and to the haste with which young trees are felled before they have attained maturity, and by the wretched condition of the roads in the island, which are never repaired, and have now become so bad that it is impossible to bring down the fine trees which are still found plentifully in the interior. In the coast districts there is no wood left.—*Chemist and Druggist.*

MISCELLANEOUS TRADE NOTICES.

Exportation of Pine-Bark from Turkey.

The Belgian *Bulletin du Musée Commercial* for the 19th November last, states that Turkish pine-bark, used for dyeing and for the preparation of skins, is now forming an important branch of exportation from the Turkish Empire. The bark is usually sent, in the first instance, either to Syra or to certain parts of Italy. For some time the exportation of pine-bark from Turkey was prohibited, at the request of the Department of Mines and Forests, but this embargo has now been removed, and the trade is once more active.

Indiarubber Trade in Holland.

The *Moniteur Officiel du Commerce* for the 10th November last states, on the authority of the Belgian Secretary of Legation at The Hague, that a few years ago there existed no india-rubber manufactory in all Holland, and that the Dutch merchants were obliged to buy all their goods either in Germany or in England. At the present time two manufactories exist, but they are far from satisfying the requirements of the country, for there are still imported annually into Holland a value of 60,000 florins in articles of india-rubber and gutta-percha. The Belgian Secretary recommends the Belgian manufacturers of these goods to make their products known in Holland.

STATISTICS.

A Few Indian Statistics.

A recent statistical abstract relating to British India contains a mass of interesting information concerning our great dependency, and is well worth the perusal of anyone who is not afraid of three hundred closely-printed pages of statistics. The total population of India, according to the census of 1881, was 253,982,595 (including 55,191,742 in the native states), occupying an area of 1,378,044 square miles; the density of population in the provinces under direct British control being more than 25 per cent. greater than in the native states. As might be expected, a larger number of people are employed in agriculture than in any other branch of occupation; the next largest section being formed by those engaged in industrial pursuits. Chemical industries give employment to 81,033 workers, 19,813 of whom are women. No less than 762,787 persons (including 273,169 women) are engaged in the collection and preparation of gums and resins. The shellac industry, which is classed in one category with ivory, bone, etc., occupies 107,996 people, but in this branch women are more than twice as numerous as men. One solitary individual among what orators call the "teeming millions" is classified as a worker in surgical instruments; but on the other hand "physicians, surgeons and druggists" are well to the fore, their combined number being 188,818, of whom 113,579 are males.

The value of the sea-borne imports into British India (excluding Government stores and treasure) was 518,115,800 Rs. in 1886, against 531,493,110 Rs. the year before; but the latter figure, it should be added, was far above the usual average. Besides the sea imports, goods to the value of 49,916,030 Rs. in 1886, 53,314,030 Rs. in 1885, and 53,112,510 Rs. in 1884, were carried into British India overland. Among the imports by sea occur the following items directly or indirectly connected with the drug trade :—

	1884.	1885.	1886.
	Rs.	Rs.	Rs.
Drugs and Medicines	362.8140	358.2780	340.0830
Dyes	251.4220	214.9520	225.7180
Glass, and Manufactures of	560.0620	499.7010	505.2040
Gums and resins	115.6770	98.8070	96.9900
Quicksilver	40.1080	10.9430	23.5610
Oils	654.2270	1,229.4960	961.1300
Paints and Colours, etc.	239.2410	201.9640	211.8060
Perfumery	61.0120	66.2700	55.7110
Spices	557.1090	602.1650	718.6780

The following are among the exports:—

	1884.	1885.	1886.
	Rs.	Rs.	Rs.
Drugs and Medicines	134.2990	199.1950	192.6050
Dyes: Indigo	4,640.9910	4,068.9000	3,783.1600
Other (except Lac)	272.5920	317.2240	469.3690
Gums and Resins	397.2010	361.8890	193.1760
Lac (Dye, Shell, etc.)	556.7380	599.9820	586.6100
Oils	520.1740	564.7460	412.1980
Opium	11,294.4600	16,882.6060	10,735.5180
Spices	400.9300	514.5800	528.5670

For Government account 130,960 Rs. worth of drugs and medicines were also imported into India in 1886, against 152,280 Rs. in 1885, and 141,330 Rs. the year before.—*Chemist and Druggist.*

AN EXPIRING PATENT.

On February 17, 1874, an English agent of Professor Hermann Kolbe, of Leipzig, was granted a patent in this country for "Improvements in the production of salicilic acid, and of the isomeric and homologous acids." The statutory period of fourteen years, during which a patentee is allowed to reap the harvest of his brains, will soon be completed, and it is expected that this circumstance will have a considerable influence on the commercial position of the acid. It will be recollected that this patent was the subject of an expensive lawsuit in 1879, when the case Von Heyden v. Neustadt occupied Vice-Chancellor Bacon for ten days. Dr. Von Heyden, who manufactured the acid by Kolbe's process in Germany, sought to restrain the defendant Neustadt from importing into and selling in this country salicilic acid, manufactured by a process identical with Kolbe's, and for which a patent had been granted in Germany. This was not denied by the plaintiff, but on his behalf it was alleged by counsel and experts that Kolbe's process was well known for many years before it was patented in this country. Kolbe first announced in 1860 that he had succeeded in preparing salicilic acid artificially by acting upon phenol with metallic sodium, simultaneously subjecting the mixture to the action of carbonic acid gas. This process was known to chemists as a beautiful one for experimental or lecture-table purposes, but no one would have dreamed of working it on a commercial scale, nor did Kolbe. But when in 1874 there seemed to be a widening outlet for salicilic acid as an antiseptic, he was ready with a modification of his process, which simply consisted of substituting caustic soda for metallic sodium. It was this new process which was patented in this country, and which was the basis of the action against Messrs. Neustadt & Co. In this action Dr. Von Heyden was successful, and since April, 1879, only Kolbe's salicilic acid, and its compounds, have been used in this country. Consequently the manufacturers could fix their own prices, and they have done so. The expiry of the patent will affect this, whether it be on account of the probable manufacture of the acid in this country or through the importation of the products of other foreign makers. By one way or the other it is almost certain that the coming year will show a substantial fall in the price of salicilic acid.—*Chemist and Druggist.*

THE SUGAR BOUNTIES CONFERENCE.

The members of the International Conference on Sugar Bounties met on the 19th December, at the Foreign Office, and adjourned until April 5th. Baron Henry de Worms presided, and all the representatives attended. The sitting occupied over three hours.

The delegates in the course of the proceedings signed the following Protocol:

"The undersigned, Delegates from Germany, Austria-Hungary, Belgium, Denmark, Spain, France, Great Britain, Italy, the Netherlands, Russia, and Sweden, met at London on November 24th, 1887, to consider the bases of an agreement relative to the suppression of bounties on the exportation of sugar.

"In the course of the deliberations set forth in the minutes of the sittings, an agreement was come to on the principles laid down in the Report of the Commission. In order to give to this agreement a practical application, the President of the Conference placed before them a Draft Convention, which they have examined, and which they pledge themselves to submit to the consideration of their respective Governments, together with a request that those Governments will make known to the Government of Her Britannic Majesty, before the 1st day of March, if they give their adhesion to the principles of this Draft Convention, which is subjoined to the present Protocol. Every Government replying affirmatively will communicate to the British Government before the above-mentioned date a Draft Statement indicating the bases of application of the system of taxation on the quantities of sugar produced. The Draft shall state with what limitations and in what cases use would be made of the saccharometer. Each Government will, at the same time, declare whether, for the sake of uniformity, it would be disposed to admit what is known as the French method, generally employed in the commerce of several nations.

"As regards Article III. of the aforesaid Draft Convention, the French being of opinion that the system proposed for Belgium does not present those guarantees for the suppression of bounties with which the High Contracting Parties are bound to protect themselves, accept this Article with every possible reservation. The Delegates of Germany, Austria-Hungary, Spain, Italy, the Netherlands, and Russia support the reservations made by the French Delegates.

"London, Dec. 19th, 1887."

"Subjoined to the Protocol of Dec. 19, 1887.

"Draft Convention.

"The High Contracting Parties, desiring to bring about the total suppression of bounties, open or disguised, on the export of sugars, have resolved to conclude a Convention to this effect, and have nominated as their Plenipotentiaries the following, to wit:

"Who, after interchange of their full powers, and finding them to be in valid and proper form, have agreed to the following Articles:—

"I.

"The High Contracting Parties pledge themselves to take or to propose to their respective Legislatures such measures as shall constitute an absolute and complete guarantee that no bounty, either open or concealed, shall be granted on the export of sugars.

"II.

"The High Contracting Parties pledge themselves to adopt, or to propose to their respective Legislatures, a system of duties on the quantities of sugar produced and intended for consumption, as the only one by which the suppression of the bounties in question can be attained, and to place under one and the same *régime* the manufacture of glucose, and the manufactures for the extraction of sugar from molasses.

"III.

"As Belgium is not under the same conditions in respect of the application of the system of duties on the quantities of sugar produced, the existing *régime* established in that Kingdom may be maintained, subject to the following modifications:—

"The amount of duty shall be reduced from 45 francs to 25 francs from and after the day when this Convention shall come into force.

"IV.

"There shall be admitted to equal rights in this Convention all such States, or Colonies, or Foreign Possessions of the High Contracting Parties, as, though not adopting the system described in Article II., do not impose duties on sugars, or who undertake not to accord to sugars for export, either raw or refined, any drawback, repayment, nor abatement of dues or quantities.

"V.

"In case any State which does not impose dues upon sugar should intend to establish them, such State shall be bound to charge these dues upon the quantity of sugar produced and intended for consumption, or, at least, to give no drawback, repayment, nor abatement of dues or quantities.

"VI.

"The High Contracting Parties will communicate to one another the laws which may have been already repealed in their respective States, or are about to be, in relation to the purpose of the present Convention.

"VII.

"The States which have not taken any part in the present Convention are permitted to join in it on application. Their adhesion shall be diplomatically announced to Her Britannic Majesty's Government, and by it to the other Signatory Powers.

"VIII.

"The stipulations of the present Convention shall be applicable to the Colonies and Possessions of Her Britannic Majesty, with the exception of those hereinafter named, to wit:—

"The East Indies, Canada, Newfoundland, the Cape, Natal, New South Wales, Victoria, Queensland, Tasmania, South Australia, Western Australia, and New Zealand.

"At the same time the stipulations of the present Convention shall be applicable to any of the Colonies or Possessions above mentioned, from the date at which the Government of Great Britain shall notify the adhesion of such Colony or Possession to the other contracting Powers.

"Any one of the Colonies or Possessions above named which may have given its adhesion to the present Convention retains the power of withdrawal in the same way as the Contracting Powers.

"In the case of any one of the said Colonies or Possessions desiring to withdraw from the Convention, a notification to that effect will be made by the British Government to the Contracting Powers.

"IX.

The present Convention shall come into force on and after   . It shall remain in force for ten years from that date, and in the event of no one of the High Contracting Parties having given notice, twelve months before the expiration of this period of ten years, of its intention to bring it to an end, it shall continue in force for another twelve months, and so from year to year.

"Should one of the Signatory Powers denounce the Convention, their denunciation will affect only the Power making it.

"X.

"The present Convention shall be ratified, and the ratifications in regard to it shall be exchanged in London within   months at the latest, and sooner if possible."

Monthly Patent List.

I.—GENERAL PLANT, APPARATUS AND MACHINERY.

APPLICATIONS.

15845 F. B. Hill and M. Shearer, London. Vacuum and pressure fluid pumps for gases. November 18

15938 R. Morris, London. Filters. November 19

16011 R. Horsburgh, Glasgow. A regenerative furnace. November 22

16016 J. Jackson, Manchester. Lead lined boilers and similar vessels. November 22

16013 J. Jackson, London. Gauges for measuring pressure or (and) vacuum. November 22

16051 R. Pol, London. Apparatus for the filtration of liquids. November 22

16220 J. Powell, London. Regenerative furnaces. November 25

16223 J. Hodgkinson, London. Furnaces for steam boilers, and mechanical stokers for supplying same with fuel. November 25

16381 H. Berghoff, London. Apparatus for filtration of liquids. November 29

16393 T. F. Cashin, Hastings. Furnaces and appliances for generating heat and steam. November 29

16534 E. Edwards—From E. Cambiaso, I. Colomba and G. N. Mangini, Italy. Apparatus for feeding coal to furnaces. December 1

16545 J. S. Sawrey and H. Colcet, London. Apparatus for separating liquids from solid matters in suspension therein. December 1

16594 J. S. Sawrey, G. E. Bellis and A. Moreom, London. Apparatus for separating liquids from solid matters suspended therein. December 2

1698 W. Mellor, Manchester. Mechanical stokers. Dec. 5

16715 J. Noble and B. H. Thwaite, Liverpool. Ingot and crucible heating arrangement. Complete specification. December 6

16787 H. E. Newton—From F. Theiser, Germany. Apparatus for condensing and cooling purposes. December 6

16805 W. T. Walker, London. Distillatory apparatus for use in chemical operations. December 6

16896 W. T. Walker, London. Apparatus to be used in chemical operations where it is required to drive off from liquids volatile constituents thereof. December 6

16952 W. H. Gilruth, London. Apparatus for treating vegetable or mineral substances to evaporate moisture therefrom. December 9

17049 I. S. McDougall and T. Sugden, London. Apparatus for effecting the separation of solid matter from fluids, applicable also for separating water or liquids from steam or other vapours or gases. December 10

17193 T. Pursall and W. Lister, Birmingham. Smoke consuming and fuel economising apparatus for boiler muffles, etc. December 14

17290 A. Knoop, London. Improvements in and relating to apparatus for evaporating brine and other solutions, for distilling or rectifying alcohol, and for similar purposes. Complete specification. December 15

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

791 A. H. W. Brown. Means for economising fuel and consuming smoke in furnaces. November 19

811 W. Waller. Steam boilers for heating and evaporating fluids. November 30

991 J. Y. Johnson—From H. J. Drory. Apparatus for spraying and burning liquid fuel. November 30

2870 J. A. Eaton—From S. H. Shaw. Apparatus for heating air to a high temperature. November 19

7772 G. W. Allen and H. J. A. Bowers. Water purifying apparatus. December 7

12169 P. Alfieri. Powder for preventing and removing incrustation in boilers. December 7

12357 R. M. Bryant. Anti-incrustation preparation. Dec. 7

13013 H. Wilson and A. Wilson. Apparatus for injecting air, gas, oil, etc., into furnaces, for increasing draught, reducing smoke, etc. December 7

14209 W. H. Rusden. Electrical apparatus for preventing corrosion and incrustation in boilers. November 23

14539 W. L. Horne. Vacuum apparatus. November 26

14758 A. Schrieber. Smokeless furnaces. November 30

15238 E. A. Cowper. Filter presses. November 8

15590 W. Creswick. Apparatus for drying, heating or cooling substances in a semi-liquid or powdered state. Dec. 17

II.—FUEL, GAS AND LIGHT.

APPLICATIONS.

15811 G. Watson, Birmingham. A hydraulic gas valve to be fixed between retorts and gas main on retort bed. Nov. 18

15852 J. H. R. Dinsmore, Liverpool. Improvements in and connected with the manufacture of illuminating gas from coal. November 18

16222 S. Cueler, London. Improvements in gas washers or scrubbers when more than one are employed. November 25

16396 J. H. Pearson, London. A method of preparing peat for firelighters and for fuel by means of preparations of coal tar. November 29

16483 J. Swift, London. An improved method for increasing the luminosity of circular flames in oil, gas or incandescent lights. November 30

16501 L. Wacks, London. An improved artificial fuel. December 1

16543 F. Pool, London. Improved appliance for scraping the insides of retorts in which gas is produced from steam and hydrocarbon, and the simultaneous removal of the deposit therefrom. December 1

16600 A. G. Browning and M. R. Waddle, Bradford. Improvements in the means or method of securing the lids of gas retorts and other similar covers. Complete specification. December 2

16631 A. F. Firth, Halifax. Improvements in or connected with pipes employed in the manufacture of illuminating gas. December 3

16866 R. Good, London. Improvements in apparatus for injecting liquids into gas retorts. December 7

17007 J. Swallow and N. Procter, Leeds. Method for converting gas-coke, smudge, small coal, and all descriptions of coal and coke residue into a flammable fuel by either hot or cold process. December 10

17223 J. Cobbe, London. Improved method of reflecting gas or other artificial light. December 14

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

16018 A. Thomas. Means for straining gas tar to be used as fuel. December 10

16053 B. H. Thwaite. Producing combustible gases from liquid hydrocarbons, and apparatus therefor. November 30

1887.

1150 J. S. Sellon. Apparatus for lighting by the consumption of gas and air. December 7

1190 J. Atterton. Apparatus for charging gas retorts. December 3

1684 W. H. Lindsay. Manufacture of artificial fuel. Nov. 23

1922 P. Haddan—From G. L. Barton. Method of refining crude and refuse petroleum and the like. November 26

1965 J. Birchall. Manufacture of gas and apparatus therefor. December 10

14531 J. Y. Johnson—From G. Mulheims and R. Zimmermann. Apparatus for moulding blocks of artificial fuel. November 26

15003 J. G. Hawkins and J. Barton. Gas retort lids, and method for ensuring gas-tight joint between the lids and mouthpieces. November 3

15009 H. W. P. Nugent. Gas retort and other furnaces.

15164 O. Knublauch. Production or recovery of cyanogen compounds from coal gas and other gases. December 14

15256 S. Pitt—From T. G. Hall. Process of refining hydrocarbon oils. December 10

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

APPLICATIONS.

16301 J. Lewkowitsch, London. Improvements in the extraction of organic bases from the distillates of coal and shale tars. November 26

16582 J. Dempster, Manchester. Improvements in apparatus employed in the continuous production or distillation of gas and other products from coal and other materials and minerals. December 2

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

16213 I. Levinstein, Manchester. A new or improved colouring matter. November 25

16484 J. Y. Johnson—From The Farbenfabriken vormals F. Bayer & Co., Germany. Improvements in the manufacture of azo dyes. November 30

16493 J. Y. Johnson—From The Farbenfabriken vormals F. Bayer & Co., Germany. Improvements in the manufacture of azo dyes. November 30

16810 R. Chadwick and J. W. C. Chadwick, London. Improved colouring matter for dyeing, painting, staining, or printing. December 6

16974 J. Imray—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, A. F. Poirrier and L. Roussin, France. Manufacture of orange and red azoic colouring matters. December 9

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

737 O. Imray—From The Farbwerke vormals Meister, Lucius and Brüning. Manufacture of colouring matters by the action of nitrosoderivatives of secondary aromatic amines upon phenols and oxycarbonic acids. December 3

1694 O. Imray—From The Farbwerke vormals Meister, Lucius & Brüning. Production of alkalised diamidobenzophenonaminechlorides, and conversion of the same into alkylised diamidobenzophenones and yellow colouring matters of the class of the "auramines." December 7

2985 O. Imray—From The Farbwerke vormals Meister, Lucius & Brüning. Manufacture of a methylene blue specially adapted for printing on textile fibres. December 17

3028 F. Raschig. Production of hydroxylamine. Dec. 14

3304 R. Reid. Separating solid matter from alizarin or other colouring matters or starch. December 10

4492 H. H. Lake—From K. Oehler. Manufacture of colouring matters. November 23

V.—TEXTILES, COTTON, WOOL, SILK, ETC.

APPLICATIONS.

15896 T. F. Wiley, Bradford. A new process or method of and apparatus for rendering textile fabrics waterproof or water-repellent. November 19

15899 T. F. Wiley, Bradford. Improvements in machinery or apparatus for water-proofing or rendering textile fabrics water-repellent. November 19

15900 T. F. Wiley, Bradford. A new or improved process and apparatus for rendering textile fabrics waterproof or water-repellent. November 19

The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

16339 A. C. Henderson—From C. Stocker, France. Improvements in the method of, and manufacture of non-inflammable cellulose matters. November 28

16653 J. B. Megemond, jun., M. E. Megemond, J. B. A. Megemond, and C. J. M. Raffard, London. Improvements in the manufacture of felt. December 3

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

5097 R. H. Collyer. Process and apparatus for preparation of rhea or other vegetable fibres for textile purposes. November 19

11182 W. J. S. Grawitz. Treatment of textile materials dyed with aniline black, December 7

VI.—DYEING, CALICO PRINTING, PAPER STAINING AND BLEACHING.

APPLICATIONS.

15972 J. Marshall, Walsden. Dyeing and painting a cotton velvet in two colours, and so producing a shot effect. November 21

16171 A. Bensinger, London. Process for producing designs on celluloid or like pyroxiline compounds. November 24

17102 G. A Schleber, London. Improvements relating to the bleaching, dyeing, and similar treatment of cloth and other fabrics, and to apparatus therefor. December 12

17106 J. Grunhut, London. An improved process and means of dyeing cotton and other fibrous substances in aniline black. December 12

17251 G. W. Liddiard, Manchester. Improved apparatus for dyeing, soaping, washing, and finishing yarn. December 15

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

818 J. Walker. Method and apparatus for dyeing or treating textile fibres. November 19

1351 W. Birch Machines for washing, soaping, dyeing, and dunging woven fabrics. November 30

VII.—ALKALIS, ACIDS AND SALTS.

APPLICATIONS.

16031 F. Foster, London. Generating carbonic acid gas. November 23

16254 The Tyne Alkali Company, Limited, and T. Gibb, London. Improvements in the treatment of solutions containing barium or strontium compounds, and the obtainment of products therefrom. November 25

17050 W. H. Beck—From P. de Lachomette, France. New or improved process and apparatus for the manufacture of sulphite and bisulphite of ammonia. December 10

17073 W. Mason and C. J. Whittaker, Accrington. Improvements in the process and apparatus for the manufacture of soda and ammonia salts by the ammonia alkali process. December 12

17095 W. White, and A. Richardson, London. Improvements in the packing of acids. December 12

17255 D. Herman, Liverpool. Improvements in condensers and towers for the condensation of acid and corrosive gases. December 15

17273 L. Mond, and G. Eschellman, Liverpool. Improvements in the manufacture of chlorine. December 15

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

1832 J. Mangnall. Generating carbonic acid gas, and apparatus therefor. December 10

1973 W. B. Cogswell. Bicarbonate columns. December 7

1974 L. Mond, and D. B. Hewitt. Manufacture of caustic soda or caustic potash, and of carbonic acid from mono or other carbonate of soda or potash. December 7

1993 E. Hermite, E. J. Patterson, and C. F. Cooper. See Class XVIII.

2966 J. J. Hood, and A. G. Solomon. Manufacture of sulphate of alumina. December 17

15164 O. Knublauch. See Class II.

VIII.—GLASS, POTTERY AND EARTHENWARE.

APPLICATIONS.

15875 S. Pitt—From M. S. Highie and G. G. Frelinghusen, United States. Improved process for the manufacture of earthenware and the compounds therefrom. November 18

16031 E. S. Baldwin—From D. Mitchell, New Zealand. An improved apparatus for cutting glass tubes. November 22

16142 G. J. Atkins, London. Improved process or means of producing a crystalline effect on the surface of glass or other vitreous substances. November 21

16168 T. Taylor, W. Tunnycliff, and W. H. Slater, Birmingham. Improvements in the ornamentation of china and earthenware surfaces. November 24

16355 J. Y. Johnson—From M. Aubriot, France. A new or improved process for producing cloisonne designs or decorations in enamelling glass and other substances. November 28

16359 E. M. Macdonald, London. An improved process or method for producing fixed drawings or paintings on porcelain, china, or on other suitable material. November 28

16487. T. W. Webb, London. Improvements in ornamenting glass. November 30

16621 J. Larmanjat, London. Improvements in the method of and apparatus for moulding, pressing, and drying tiles having inlaid patterns. December 2

16951 E. Stiff, Lambeth. Constructing water-tight tanks, cisterns, tuns, vats, and other vessels, of slabs of earthenware or other suitable material. December 9

16980 F. V. Macquaire, London. An improved refractory compound. December 9

17066 M. Erlich and C. Storck, Berlin. Improvements in the method of printing gold, silver, or platinum decorations on ceramic articles. Complete specification. December 12

17125 A. D. Brogan and A M. Malloch, Glasgow. Improvements in apparatus for rolling plate glass to produce rippled, dappled, vermicular chequered, or other patterns or designs thereon. December 13 .

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

12076 T. C. J. Thomas. Manufacture of glass. November 23

1887.

967 W. Cliff. Manufacture of fire-clay enamelled baths. November 23

1131 D. Rylands and B. Stoner. Means for blowing bottles or other hollow glass-ware. November 30

1441 P. Graham. Manufacture of hollow clay-ware, and "jollies" or machines therefor. December 3

2305 H. L. Doulton and W. P. Rix. Ornamenting pottery, tiles, or glass. December 14

3434 H. M. Ashley. Manufacture of bottles and other hollow glass-ware, and machinery therefor. December 17

9291 M. F. L. Ehrlich & Co., and C. T. Storck. Producing decorations in gold, etc., on pottery

13723 C. Amand-Durand and R. P. Engelmann. Decorating glass, and apparatus therefor. December 3

15096 S. Fenn and A. Fenn. Fireplaces of kilns or ovens for burning bricks, pipes, terra-cotta, etc. December 14

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

APPLICATIONS.

15926 O. Bowen, London. Improvements in the manufacture of Portland cement. November 19

16117 S. J. Payne, West Shurrock. The improvement of the manufacture of hearthstones or similar kind of goods. November 23

16746 W. G. Watson, Heaton, and J. Judge, Wallsend. An improved machine for dressing and finishing building bricks, flooring tiles, and other clay articles. December 6

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

678 E. W. Jones and C. Brand. See Class X. November 19

14897 P. von Krystoffovitch. Manufacture of artificial granite. December 3

X.—METALLURGY, Etc.

APPLICATIONS.

15857 R. R. Gubbins, London. Improvements in treating or piling wrought scrap iron. November 18

15881 C. A. Meygret and P. Marino, London. A new alloy and process for manufacturing the same, and for electroplating and typing therewith. November 18

15884 J. Ashworth, Manchester. Improvements in or relating to miners' safety lamps. November 19

15931 W. Davis, Sheffield. Improvements in and apparatus and appliances for the manufacture of steel plates with thickened edges. November 19

16027 C. E. Tripler, London. Improvements for amalgamating and separating precious metals from powdered ore or earth. Complete specification. November 22

16118 L. A. Brode, Glasgow. Improvements in the manufacture of bricks or blocks of ironstone waste or dust, or ironstone, sand, or similar ferruginous materials for smelting. November 21

16183 J. B. Spence, London. Improvements in the treatment of ores containing gold for the purpose of extracting the gold therefrom. November 24

16192 J. P. Ogle, London. An improved arrangement of the amalgamated plates employed in the treatment of gold ores, in the supports for the same, and in apparatus connected therewith. November 24

16270 H. Hutchinson, London. Improvements in the treatment of refractory gold and silver ores. November 26

16346 H. B. Scott and W. Gentles, London. Improvements in tuyéres for blasts of furnaces, and for agitating molten material. November 28

16347 H. B. Scott and W. Gentles. Improvements in the smelting of copper and lead ores, and arrangement of furnaces for that purpose. November 28

16436 G. J. Snelus, London. Improvements in the manufacture of steel, and in apparatus therefor. November 29

16491 H. W. Buddicom, London. Improved apparatus for dipping or cleansing tin or terne plates. November 30

16495 W. R. Lake—From A. Vogelmann, Germany. Improvements in apparatus for extracting metals from their ores. Complete specification. November 30

16497 B. H. Thwaite and J. Noble, Liverpool. Improvements in the manufacture of steel, and in plant therefor. Complete specification. December 1

16553 A. Schanschieff and D. Marks, London. Improvements in extracting gold, silver, and other metals from their ores and alloys. December 1

16601 A. S. Ramage, Liverpool. Improvements in or relating to the chemical treatment or utilisation of scrap tin, or terne plates, scrap zinc, galvanised iron, and the like. December 2

16611 F. Caulfield and A. Allan, Glasgow. Improvements in preparing, compressing, and uniting materials for smelting purposes. December 3

16727 A. B. Cunningham, London. Improvements relating to the production of aluminium and aluminium alloys. December 5

16745 J. Noble and B. H. Thwaite. See Class I.

16770 W. Wood, London. Miners' safety lamps. December 6

16771 A. Fieldsend and J. E. Bott, Manchester. Improvements in the manufacture of crucible steel, and apparatus therefor. December 6

16781 W. Pilkington, London. Improvements in the manufacture of steel and iron shells for ordnance and machine guns. December 6

16828 A. J. Ash, Birmingham. Improvements in coating metals with zinc, tin, terne, and other coating metals. December 7

16853 W. L. Wise—From the Schweizhische Metailurgischie Gesellschaft of Lautfen, Switzerland. Improvements in apparatus for producing alumina and other metals and their alloys, and operating the same. December 7

16862 E. J. Ball and B. H. Brough, London. Improvements in appliances for amalgamating auriferous and argentiferous substances. December 7

16901 L. A. Groth—From J. Lotineaux, Paris. Improvements in safety lamps for miners. Complete specification. December 8

16910 C. M. Pielsticker, London. An improved method and apparatus for the production of metal bars direct from the molten metal. December 9

16911 C. M. Pielsticker. The removal of blow-holes from metals. December 9

16979 T. Anderson, London. Improvements relating to the tinning of hollow-ware and other articles. December 9

16991 J. Walls, Hindley Green. Improved miners' safety lamps. December 10

17033 A. Parkes, London. Improvements in the extraction of gold and silver from ores or compounds containing the same, and in solvents for such metals. December 10

17036 W. D. Allen, London. Improved means for carrying, turning, and otherwise manipulating ingots of iron or steel in the process of beating and forging. December 10

17037 W. Robinson, London. Improvements in ingot moulds. December 10

17111 M. Gledhill, London. Improvements relating to the casting of hollow metal ingots, and to apparatus therefor. December 12

17156 J. Bedford, London. Improved methods or processes of treating or purifying alloys of iron and manganese and other metals, for use when so purified in admixture with other materials. December 13

17169 D. Edwards, R. Lewis, and P. Jones, London. Improvements in apparatus for coating metal plates with tin or other metal. December 13

17288 S. Siemaug, London. Improved manufacture of compound castings for armour-plates and other purposes, and apparatus therefor. December 15

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

14308 J. H. James. Crushing and dressing tin and other ores, and machinery therefor. December 10

15477 E. Morewood. Coating sheets or pieces of iron or other metal with tin or other coating metal. November 26

16109 S. F. Walker. Miners' electric safety lamps. Dec. 14

16608 D. G. Fitzgerald. Production of coherent masses of peroxide of lead for use as battery elements, and in electrolytical and metallurgical operations. December 3

17649 K. W. E. Maruhn. Reducing slag and recovering metal therefrom. December 14

1887.

298 T. Allen. Machine for forging or shaping metal articles. December 3.

678 E. W. Jones and C. Brand. Manufacture of paving blocks from scoria or slag, and means therefor. Nov. 19

803 P. M. Justice—From W. V. Shelton. Production of alloys or bronzes. November 19

913 A. E. Tucker and F. W. Harbord. Manufacture of iron and steel. November 23.

1134 J. A. Yeadon and R. Middleton. Blocks or briquettes of fuel for smelting or analogous purposes. December 11

1261 D. McCorkindale and G. Dougall. Stoppers used in the manufacture of steel. November 26

1276 E. Cleaver. Manufacture of aluminium and aluminium alloys. November 30

2060 W. Gentles. Manufacture of copper. December 10

2935 J. Dickson. Preparing steel for roller bars and bed-plate bars for manufacture of paper and paper pulp. Dec. 14

4583 R. H. W. Biggs. Manufacture of dyes, disinfectants, artificial stone, artificial ivory, artificial manure, sodium chloride, zinc sulphate, and zinc carbonate. November 23

9231 J. Toussaint. Manufacture of wrought iron and steel, and apparatus therefor. December 10

14792 H. J. Allison—From J. B. D'Arcy Boulton. Casting metallic ingots. December 3

XI.—FATS, OILS AND SOAP MANUFACTURE.

APPLICATION.

16329 F. Rainbow, Luton. Incorporating mineral oils known as kerosine and petroleum oils into soap, or mixing with soaps. November 28

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

16925 Sir D. L. Salomons. Buoyant soap. November 26

1887.

1291 N. M. Henderson. Apparatus for treating or purifying paraffin wax. November 30

15054 M. J. Hortung and W. Gallagher. Lubricating oils and greases. December 7

XII.—PAINTS, PIGMENTS, VARNISHES AND RESINS.

APPLICATIONS.

15835 T. D. Harries, Aberystwyth. Enamelled composition. November 18

16263 F. M. Spence and D. D. Spence, Manchester. Improvements in the manufacture of certain pigments, and in the manufacture of certain products obtained in connection therewith. November 26

16894 S. J. Cluff, Dublin. Improvements in blacking. Dec. 8

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

955 H. H. Gunn. Manufacture of sulphide of zinc white. November 30

1382 E. Page and G. Brayfield. Composition for varnishing and reviving leather. November 30

XIII.—TANNING, LEATHER, GLUE AND SIZE.

APPLICATIONS.

15811 J. J. Carr, Scarborough. An improved paperhangers and painters' combined paste and size. November 18

15851 J. Palmer, London. An improved solution and treatment for unhairing hides and skins and preparing them for tanning. November 18
16469 F. H. Colley, Sheffield. Improvements in the process of tanning. November 30
17103 E. J. Lanvin-Schraen, London. Improvements in tanning and apparatus therefor. December 12

COMPLETE SPECIFICATION ACCEPTED.

1887.

1009 A. Smetham. Manufacture of waterproof leather. November 23

XIV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

17094 H. D. Salomonson and J. Laubheimer, London. Improvements in machines with spiked appliances for reducing or pulverising superphosphates and other materials. Dec. 12
17181 L. G. G. Dandenart, Liverpool. Improvements in the method of manufacturing hydrated phosphates, and in apparatus therefor. December 14

COMPLETE SPECIFICATION ACCEPTED.

1887.

15309 J. Davenport. Manufacture of fertilisers or manuring compounds. December 10

XV.—SUGARS, GUMS, STARCHES, Etc.

APPLICATION.

16732 E. Breyer, London. Improvements relating to the purification of saccharine juices, glycerine, oil, alcohol and analogous substances. December 5

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

688 J. Karpeles. Process and means for concreting amber shavings. November 19
986 V. C. A. M. Bondonneau and A. J. M. G. Foret. Process and apparatus for acid saccharification of starchy materials. November 23
2572 C. D. Abel—From T. Rousselot. Multiple three-roll sugar-cane mills. December 7
2905 H. H. Lake—From La Compagnie de Fives-Lille. Diffusing apparatus for use in the treatment of beet-root, sugar-cane, etc. December 17
3304 R. Reid. See Class IV.

XVI.—BREWING, WINES AND SPIRITS.

APPLICATION.

15995 C. Billing, Liverpool. New or improved wines or beverages. November 21

COMPLETE SPECIFICATIONS ACCEPTED.

1886.

17059 W. Gerdes. Treament of waste products of brewers for production of alcoholic liquor. November 23

1887.

1516 W. Adlam and F. Faulkner. Treating brewers' wort, and apparatus therefor. November 30
2005 C. Church. Brewing. December 3
2109 H. Grote. Process for removing fusel oil from crude spirits, or from the mash containing crude spirits. December 10
11232 R. Ranger. Apparatus for regulating the surface flow of wort from coolers. November 23
14737 T. G. Bowick. Purifying alcohols by means of hydrocarbons, and apparatus therefor. December 14

XVII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, DISINFECTANTS, Etc.

APPLICATIONS.

A.—Chemistry of Foods.

15832 R. H. Courtenay, London. An improved method of preparing and desiccating fruit and other substances in combination with whole meal from cereals and nuts, without the use of sugar in the prepared compounds. November 18
16100 W. H. Wells, Evershot. An improved dairy method for treating milk and its products. November 23
16592 C. R. W. Offen and A. T. More, London. Improvements in preventing the second or further fermentation of yeast, or any other ferment or raiser, where combined with wheat or any other cereal or admixture of cereals to be consumed or used as food. Complete specification. December 2
16652 F. Graeff, London. Improved method of preparing ferment of rennet. December 3
16935 C. Collin and L. Benoist, London. An improved method or means of preserving and preventing the putrefaction of animal and vegetable substances. Complete specification. December 8
16964 A. R. Rooson, London. An improvement in or relating to the preservation of fish and other substances, and a novel preparation of antiseptic material for use therefor or for other purposes. December 9
17268 M. Frischer, London. A composition of matter to be used as a preserved food. December 15

B.—Sanitary Chemistry.

15939 W. Webster, jun., London. Improved apparatus for the electrolytic treatment of sewage and other impure liquids. November 19

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1886.

15674 T. B. Brodbelt. Manufacture of cheese and apparatus therefor. November 30

1887.

1772 J. France. A new treatment of milk to prevent its turning sour. December 7
9950 L. Stollwerck, C. Stollwerck, and F. Baumer. Preserving fruit, vegetables, and other articles of food. Dec. 3
13049 I. Allegretti. A preserving system for perishable articles. December 14
14744 E. Scherff and C. Dreukham. Condensing milk and other fluids containing protein, and preserving same. Nov. 30

B.—Sanitary Chemistry.

1886.

12259 R. de Soldenhoff. Desiccation, incineration, etc., of precipitants of solids resulting from sludge or other substances liable to putrify, and apparatus therefor. November 26
16039 W. H. Hartland. Treating sewage and waste liquids for recovery or manufacture of manurial products, and apparatus therefor. December 7

1887.

1699 D. Craig. Utilising sewage sludge. December 7
2103 C. Wigg. Treatment of spent copper liquors and the application or the product for the purification of sewage and like matters. December 17
14857 A. Engle. Furnace and process for burning wet and offensive substances. December 7

XVIII.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

15858 W. Main, London. Improvements in dynamo-electric machines and electro-motors. Complete specfication. Nov. 18
15939 W. Webster, jun. See Class XVII. B.
15943 O. C. D. Ross, London. Improvements in galvanic batteries. November 19
16032 W. Main, London. Improvements in electro-motors and dynamo-electric machines. Complete specification. Nov. 22
16120 E. Tyer, London. An improvement in voltaic batteries. Complete specification. November 23

16124 T. J. Jones, London. An improvement of voltaic batteries. November 23

16296 A. F. St. George and C. R. Bonne, London. Improvements in primary and secondary galvanic batteries. Nov. 26

16305 H. C. Donovan and T. Weatherall, London. An improvement in voltaic cells. November 26

16455 H. Thame, London. Improvements in secondary or storage batteries. November 30

16669 M. Bailey and J. Warner, London. An improved secondary battery combined with a miner's lamp. Complete specification. December 3

16709 T. A. Edison, London. Improvements in electrical generators. Received December 5. Antedated June 13, under International Convention.

16849 G. A. Schoth, London. Improvements in the manufacture of galvanic batteries. December 7

16926 T. Fenwick, London. Improvements in the electrodepositions of metals. December 8

17097 F. Kinn, London. Improvements in secondary batteries. December 10

17157 H. H. Lake.—From J. O. Whitten, United States. Improvements in galvanic batteries. Complete specification. December 13

17186 R. E. Hides, Sheffield. An improved process of ornamenting metallic and other surfaces by the electro-deposition of metals. December 14

COMPLETE SPECIFICATIONS ACCEPTED.

1887.

700 L. Z. de Ferranti. Electric furnaces and apparatus for heating, lighting, and carrying on chemical processes. Dec. 17

1738 C. D. Abel—From Siemens and Halske. Dynamo-electric machines. December 23

1862 C. D. Abel—From A. Dunn and F. Hasslacher. Secondary batteries. December 7

1929 C. D. Abel—From A. Dunn and F. Hasslacher. Galvanic batteries. December 7

1993 E. Hermite, E. J. Paterson, and C. F. Cooper. Apparatus for electrolysing bleaching solution. December 10

14901 C. R. Goodwin. Electric batteries. December 3

15730 J. Vaughan-Sherrin. Galvanic batteries. Dec. 17

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATION.

17096 W. Black and W. Rennoldson, London. An improvement in the manufacture or preparation of materials for use in paper making and the like. December 12

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

APPLICATIONS.

16700 C. Wilson, Grimsby. Improvements in the manufacture of chemicals and medicinal tablets, pearls, and effervescing or other lozenges. December 5

16987 E. B. Ellice-Clarke and L. Chapman, London. Improvements in apparatus for the production of oxygen and nitrogen gases from atmospheric air. December 9

XXI.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

16083 W. H. Percival, London. Self-extinguishing or semi-inflammable match that can be applied to any kind of match. November 23

16116 E. Grüne, London. Improvements in the manufacture of Kieselguhr-dynamite. Complete specification. Nov. 23

16353 H. C. Zappert, London. Apparatus for dipping match splints for applying to them the ignitable tips or heads. Nov. 28

16453 J. A. Wanklyn, H. M. Maclure, and W. A. Brynn, London. Smokeless gunpowder. November 20

16721 W. P. Thompson—From the Compagnie Générale des Explosifs Favier, Belgium. New or improved explosive compounds, and improvements in or relating to the formation of cartridges thereof. Complete specification. December 5

16783 C. F. Hengst, London. Smokeless gunpowder. Dec. 6

16919 A. N. Newton—From A. Nobel, France. Improvements in detonators. December 8

16920 A. V. Newton—From A. Nobel, France. An improved explosive compound. December 8

17276 J. Y. Johnson—From F. C. Glaser, Germany. Improvements in the manufacture of explosives. December 13

COMPLETE SPECIFICATION ACCEPTED.

1887.

2318 H. H. Lake—From the Deutsche Sprengstoff Actiengesellschaft. Gelatinising nitro-glycerine. December 14

XXII.—ANALYTICAL CHEMISTRY.

APPLICATION.

17030 J. G. Jourdan, London. Improved apparatus for ascertaining and measuring the density or pressure of vapours and gases. December 10

9. 9.

Printed and Published by Emmott & Co., New Bridge Street, Strangeways, Manchester, for the Society of Chemical Industry.
London Office, for the Sale of Copies and Receipt of Subscriptions: 6, York Street, Covent Garden
